4.2.2 user-ip-restrictions.json 366
4.2.3 vlc.properties 368
4.2.4 client.properties 374
4.2.5 satnms.rc 379
4.2.6 system.name 380
4.2.7 traprec.json 380
4.3 Event Database Configuration and Event Notification Add-Ons 383
4.3.1 Event To Serial Notification 384
4.3.2 Event To Mail Notification 385
4.3.3 Event To Script Notification 386
4.3.4 EDB.properties 387
4.4 Remote Control 388
4.4.1 SNMP Control 388
4.4.1.1 SNMP Parameter Translations 390
4.4.1.2 Configuring the SNMP Agent 392
4.4.1.3 The 'create-snmp.template' Utility Program 394
4.4.1.4 The 'create-satnms.mib' Utility Program 395
4.4.2 TCP/SSL Remote Control 395
5 Installation 398
5.1 Installation Base Debian Linux 398
5.1.1 Requirements 399
5.1.2 For the impatient 399
5.1.3 Installation 399
5.2 Installation MNC Service 403
5.2.1 Requirements 403
5.2.2 For the impatient 403
5.2.3 Installation 404

5.2.4 Configuration 405
5.3 Installation Backend Service 408
5.3.1 Requirements 408
5.3.2 For the impatient 409
5.3.3 Installation 409
5.3.4 Configuration 411
5.4 Installation SatDB database 414
5.4.1 Requirements 415
5.4.2 For the impatient 415
5.4.3 Installation 415
5.4.4 Configuration 417
5.4.5 PostgreSQL network configuration 419
5.4.5.1 Change users password 420
5.4.6 Manual configuration 420
5.4.6.1 Manual add database user 420
5.4.6.2 Create SatDB database 421
5.4.6.3 Load SatDB database schema 421
5.4.6.4 Force database version 422
5.4.6.5 Delete database user 422
5.4.6.6 Remove database 422
6 Theory Of Operation 424
6.1 M&C Concept 424
6.1.1 Parameter Messages 426
6.1.2 Device Drivers 427
6.1.3 Device Driver Variables 429
6.1.4 Device Driver Procedures 429
6.2 Event Logging 430
6.2.1 Concepts 430
6.3 Automating Procedures With Macros 431
6.3.1 Concepts 432
6.3.2 Macro Directives 433
6.3.3 Timing Issues 434
7 Device Driver Reference 436
7.1 Understanding the device driver 437
7.1.1 Variables 438
7.1.2 Procedures 439
7.1.3 Protocol encapsulation 439
7.2 Writing a device driver 440
7.2.1 Starting from scratch 440
7.2.1.1 General file format 441
7.2.1.2 Naming a device driver 441
7.2.1.3 Selecting a communication protocol 442
7.2.1.4 File includes 443
7.2.1.5 Tweaking the processing sequence 444
7.2.2 Defining variables 444
7.2.2.1 The VAR statement 445
7.2.2.2 The ALARM statement 450
7.2.2.3 Info variables 451
7.2.2.4 Setup variables 452

7.2.2.5 Variables for internal use 453
7.2.3 Using conversion tables 453
7.2.3.1 The TABLE statement 454
7.2.4 Adding data exchange procedures 454
7.2.4.1 The PROC statement 455
7.2.4.2 ASYNC procedures 457
7.2.5 Basic I/O functions 459
7.2.5.1 The PRINT statement 460
7.2.5.2 The INPUT statement 463
7.2.5.3 The WRITE statement 467
7.2.5.4 The READ statement 471
7.2.5.5 Function tables in I/O functions 475
7.2.6 REST I/O functions 476
7.2.6.1 The REST TRANSACT statement 479
7.2.6.2 The REST PARSE statement 480
7.2.6.3 The REST SET statement 482
7.2.6.4 The REST CLEAR statement 486
7.2.6.5 The REST SEND statement 486
7.2.7 Conditional execution 487
7.2.7.1 The IF statement 487
7.2.7.2 The GOTO statement 487
7.2.7.3 Label definition 488
7.2.8 Using subroutines 488
7.2.8.1 The CALL statement 489
7.2.9 Manipulating variables 489
7.2.9.1 The SET statement 490
7.2.9.2 The BITSET statement 490
7.2.9.3 The RANGESET statement 491
7.2.9.4 The BITSPLIT statement 495
7.2.9.5 The BITMERGE statement 495
7.2.9.6 The SEND statement 495
7.2.9.7 The COPY statement 496
7.2.10 More statements 496
7.2.10.1 The DELAY statement 497
7.2.10.2 The LOG statement 497
7.2.10.3 The DRATE statement 498
7.2.10.4 The SRATE statement 499
7.2.10.5 The WRITEHEX statement 500
7.2.10.6 The READHEX statement 501
7.2.10.7 The INVALIDATE statement 501
7.2.10.8 The SYNC statement 501
7.2.10.9 The RAISECOMMFAULT statement 502
7.3 The RPN language extension 502
7.3.1 The RPN stack 503
7.3.2 The { ...} statement 504
7.3.3 RPN command reference 505
7.4 SNMP device classification and variable binding 510
7.4.1 Device driver syntax for SNMP definitions 510
7.4.2 List of SNMP device classes and OID names 512

7.5 Device driver examples 515
7.5.1 NDSatCom-KuBand-Upconverter Example 515
7.5.2 Tandberg-Alteia Example 517
7.6 Device communication protocols 531
7.6.1 Writing a communication protocol definition 532
7.6.2 General file format 533
7.6.3 Global definitions 534
7.6.4 TX message elements 535
7.6.4.1 CHAR 536
7.6.4.2 ADDRESS 536
7.6.4.3 USERDATA 536
7.6.4.4 CHECKSUM 537
7.6.4.5 DATALENGTH 538
7.6.4.6 HEXLENGTH 538
7.6.4.7 SEQUENCE 538
7.6.5 RX message elements 539
7.6.5.1 START 539
7.6.5.2 CHAR 539
7.6.5.3 ADDRESS 540
7.6.5.4 USERDATA 540
7.6.5.5 STRING 541
7.6.5.6 CHECKSUM 541
7.6.5.7 DATALENGTH 543
7.6.5.8 HEXLENGTH 543
7.7 Device oriented user interface 543
7.7.1 How the software finds the screens for a device 544
7.7.2 Creating new screens 544
7.7.3 Creating a 'frame' definition 545
7.7.4 Icon reference 546
7.8 Online Help 549
7.8.1 Help file format 549
7.8.2 Rebuilding the online help 553
7.8.3 Adding help files for new devices 554
7.9 ServiceClient library 554
7.9.1 Adding new devices or device types to the library 555
7.9.2 Adapting the appearance of the ServiceClient 555
7.9.3 File format of definitions.xml 555
7.9.4 Device type definitions 555
7.9.4.1 Parameters 555
7.9.4.2 Implementations 555
7.9.5 GUI constants 555
7.10 Reference Tables 558
7.10.1 Device driver keyword reference 558
7.10.2 Protocol definition keyword reference 562
7.10.3 Help file keyword reference 563
7.10.4 Debugging with Terminal Session 564
7.10.4.1 Terminal Session Commands 564
7.10.4.2 Device Message Commands 569
7.10.5 Global faults 571

This is the ***sat-nms*** MNC Monitoring & Control System user manual, describing the operation, configuration and installation of all components of the ***sat-nms*** MNC software framework.

This version of the user manual is the complete edition with all topics included. For the convenience of the reader we also provide splitted manuals covering on a subset of ***sat-nms*** MNC system.

These subsets are:

- ***sat-nms*** MNC WebClient user manual
- ***sat-nms*** MNC Legacy Java client user manual
- ***sat-nms*** MNC Installation and administration manual
- ***sat-nms*** MNC API documentation
- ***sat-nms*** MNC Universal device driver language reference manual
- ***sat-nms*** MNC Device driver reference

Support and Assistance

If you need any assistance regarding the ***sat-nms*** software, do not hesitate to contact us. We would be pleased to help you.

1 Overview

Abstract

This is the online user manual describing the ***sat-nms MNC*** monitoring & control system.

There is also a PDF version of this document, but we recommend to read the documentation online, as the user manual makes extensive usage of hyper-links which help you to jump quickly to topics which are related to that one you're actually reading.

The main sections of the user manual are:

- M&C Operation with Web Client The easy to use web browser based user interface the The ***sat-nms*** M&C System contains manifold features and functions. This section of the manual first gives a short introduction, describes the user interface and functions in detail.
- M&C Operation with Legacy Java Client Beside the new web client the system supports the legacy Java client application. This chapter describes the functionality of this client for your reference in existing installation not upgrade to the ***sat-nms*** web client.
- Administration This chapter explains in details aspects of the administration of all components of the ***sat-nms*** Monitoring & Control System. This includes for example backups, updates and a reference for all configuration files.
- Installation Usually SatService delivers pre-installed system with all components ready to use. This chapter is indended for
  the case that software components should be installed on customer provided bare metal servers or virtual machines and to provide a better understanding about the different components.
- Device Driver Reference Device drivers are the bridge between equipment and M&C system. The ***sat-nms* Universal Device Driver Language described in this chapter allow to define these drivers.
- API Reference the ***sat-nms*** backend service provides a REST-API to all function and data of the M&C system. This chapter is the complete reference to all API end points and data structures.
- Device Driver Descriptions This chapter include a full list of all device drivers with a short help page how to setup these devices and which parameters are available. Beside this it contains for logical devices detailed instructions on how to use them.

If you are not familiar with this Web based online help system, you may want to read the following chapter How To Use The Online Help, which briefly explains how to navigate thru the online help.

1.1 Using The Online Help

The user manual of the ***sat-nms*** software is built as a large set of hyper-linked web pages. These help pages are available

- on installed M&C systems via web and java client

- in the Internet at <www.satnms.com> or <www.satservicegmbh.de>
- inside the installation package `satnms4-documentation`

Invoking The Online Help

Most pages in the web client and java client contain a help button in This button opens the web browser installed on your computer and shows the help page explaining the features of the window where you clicked to the help button. Once you are in the online help system, you may use the hyper-links to navigate.

The Navigation Buttons

Every documentation page show three navigation buttons right beside the text which let you move thru the manual:

Function	Icon	Description
next		Advances to the next page within the logical structure of the user manual. This is useful if you want to read the online help like a book, page by page.
back		Goes one page back. Don't confuse with the browsers `back` button, which recalls the page you recently have watched.
menu		Jump to the table of contents page.

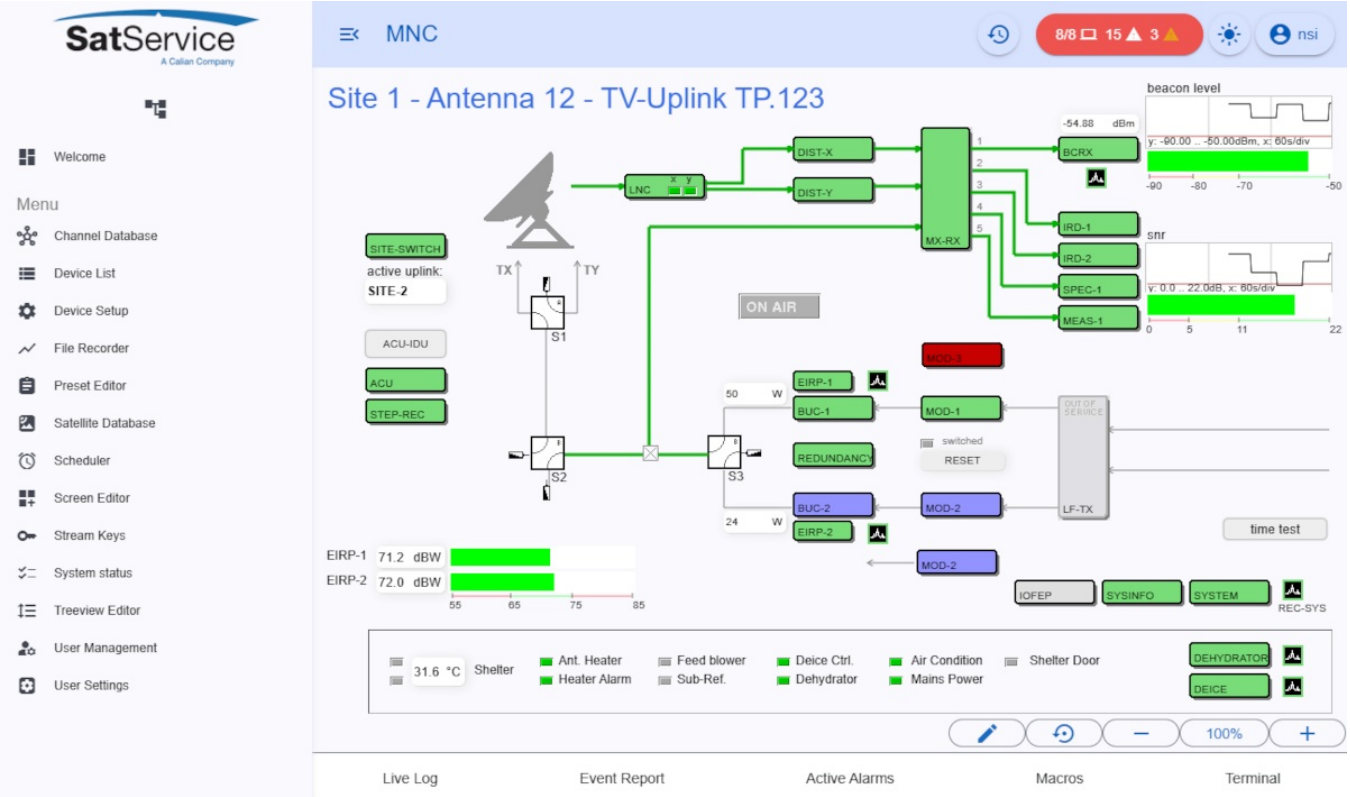
1.2 Architecture

The following chapters will give an overview about the **sat-nms** MNC Monitoring & Control system architecture and all the components.

TODO

2 M&C web-client

This section describes the functionality and the usage of the sat-nms M&C software when operated with the web-client. The following chapters of the manual describe each function and each user interface screen in detail.

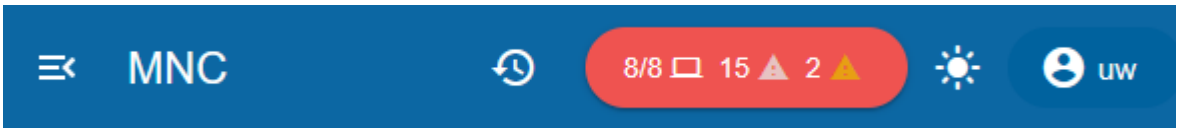


Quick access links to the main sections of the document:

- Top toolbar and Sidebar / Main Menu ok!!!
- Main window ok!!!
  - Display elements ok!!!
  - Device details panel ok!!!
  - Device window ok!!!
- Treeview ok!!!
- Channel database ok!!!
- Device list ok!!!
- Device setup
- File recorder
- Preset editor
- Satellite
  - Satellite list
  - Satellite operator list
  - Antenna
- Macro scheduler

- Screen editor
- Stream keys
- System status
- Treeview editor
- User management
- User settings
- Bottom panel

2.1 Top toolbar



Located on top of the page and permanently visible and it provides quick access to the user menu, MNC notifications etc. It can change the color from blue to red if you have configured that in user-settings warning section to show the fault state of the system.

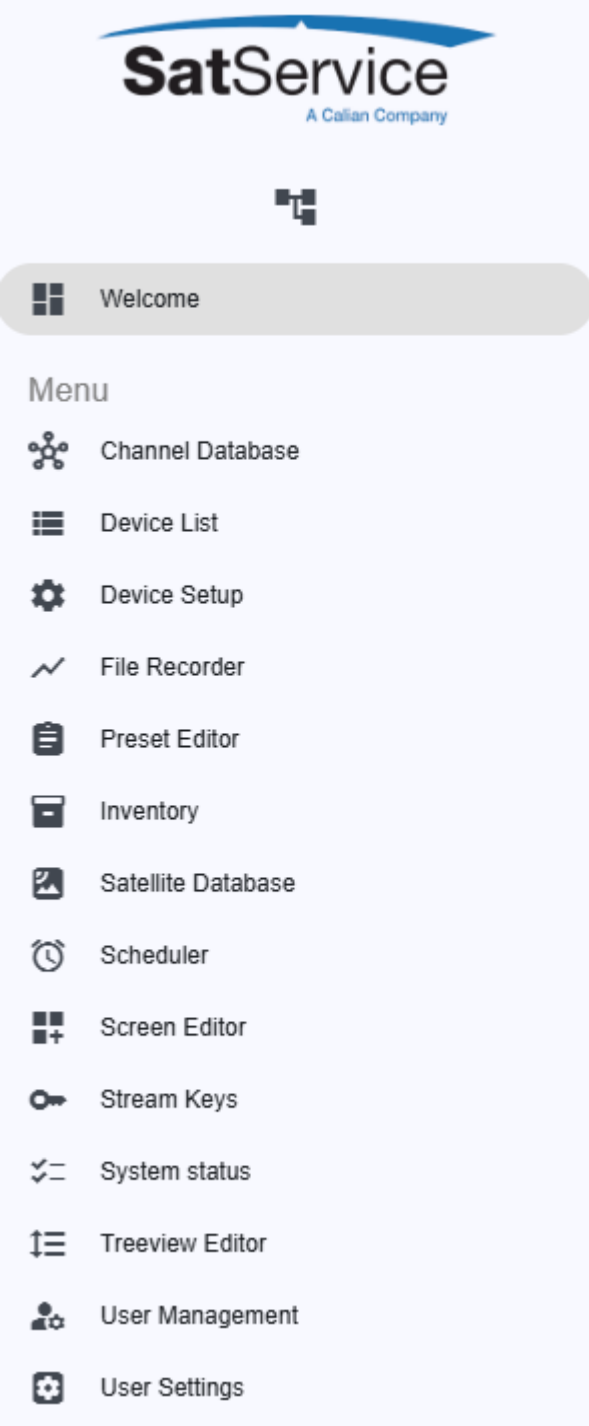
The following functions are available by clicking on the elements:

icon	description
	toggles visibility of sidebar (main menu) on the left
	shows the page history
notification area	show list of MNCs and active faults
	switch UI theme (dark mode)
	opens the user menu

2.1.1 Sidebar / main menu

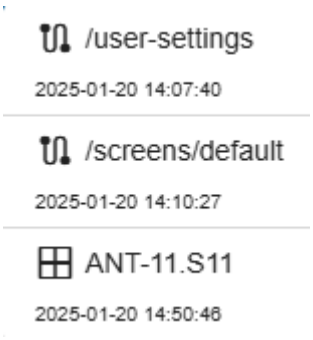
The side bar provide shortcuts to the different functions of the***sat-nms*** MNC system. It a kind of menu menu which gives you quick access to key areas and can be find on the left hand side. All menus are explained in the separates chapters.

You can hide the sidebar by clicking on the button in top toolbar



2.1.2 History

Clicking on the history button opens the list with your navigation history. If you click on a list entry you jump directly back to the listed page. This could be page from the main menu, a user screen or a device window.



Each list entry show the type (by icon), the name of the page (URL) or the name of the device. The timestamp in UTC corresponds to the time when the item was visited.

icon	description
	jump to a page or user screen (URL)
	opens specified device window

Remark: After reloading the page, the history is deleted.

2.1.3 Notification area

It gives you a clear view to the state of all connected servers and devices. Starting from left: The background color shows the summary fault state of the complete installation. The color is priorized in the following order (from low to high):

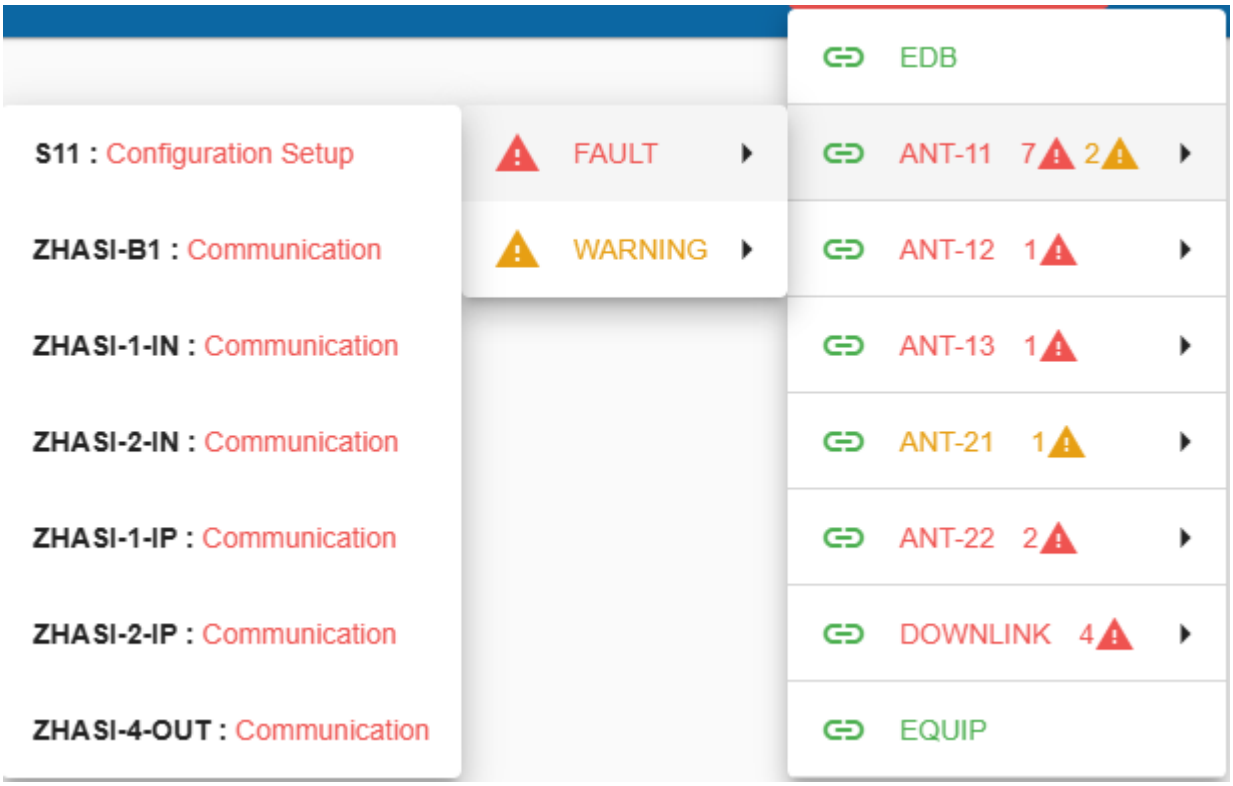
- **green**: no active alarm or warning
- **orange**: at least one device is in warning state
- **red**: at least one device is in fault/alarm state

The number inside the notification represents the following information:

- **MNC count**: number of MNC servers is displayed on the left-hand side of the computer icon
  - left number: currently connected/reachable MNCs
  - right number: total number of MNCs
  - e.g. 6/10 means 6 of 10 MNC services are currently reachable
- **Alarm count**: total number of active alarms
- **Faults**: total number of active faults
- **Warnings**: total number of active warning

If there is a new fault arriving, the corresponding symbol will be start blinking. Clicking on it will stop blinking and/or stop alarm tone.

On click it shows a dropdown list with MNC names with details about MNCs and active faults



The first level of this drop down menu show the list of configured MNC services. Clicking on such an entry will open the default user screen associated with this MNC (if configured)

- **Status indication (Icons)**
  - **Green link icon**: The MNC is connected.
  - **Red link off icon**: The MNC is disconnected.
- **Green name**: MNC have no alarms, faults and warnings.
- **Red name**: MNC have alarm(s) or fault(s).
- **Yellow name**: MNC have warning(s).
- Numbers beside each MNC name indicate the total of alarms (red), faults (red) and warnings (yellow).

When a MNC has alarms, faults or warnings, a secondary dropdown appears with the following options:

- **Alarms/Fault/Warning** per MNC
  - **ALARMS**: Displays a list of devices with alarms.
  - **FAULT**: Displays a list of devices with faults.
  - **WARNING**: Displays a list of devices with warnings.

Selecting the error type opens the 3rd level with a list of affected devices. Clicking on an entry will open the matching device in the device details panel.

After selecting the type `ALARMS`, `FAULT` or `WARNING` a list of affected devices is shown along with a brief error description

2.1.4 Theme

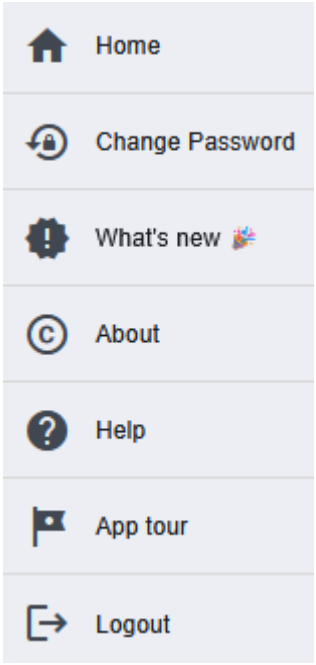
This icon shows current theme of this app. On clicking shows the following options:

- **Auto**: App will adapt the system theme.
- **Dark**: Activates dark mode.
- **Light**: Activates light mode.

2.1.5 User menu

Near the profile icon is the logged-in username. By clicking on name the user menu expands and provides the following options:

- **Home**: navigate to the default page.
- **Change password**: open the dialog to change the password.
- **What's new**: new features and improvements are listed in this sections. It's open a panel on right hand side with details.
- **About**: open about page. It contains app information like company name, address, app version etc.
- **App tour**: start the app tour and navigates through the app and it's features.
- **Logout**: logout the current user.



2.2 Main Content Window

The Main Window is the central area of the application where all content and pages are displayed. It serves as the primary **workspace** where users interact with the application’s functionality. Whether it's data views, editors, user-screens, or any other content, everything is presented within this section.

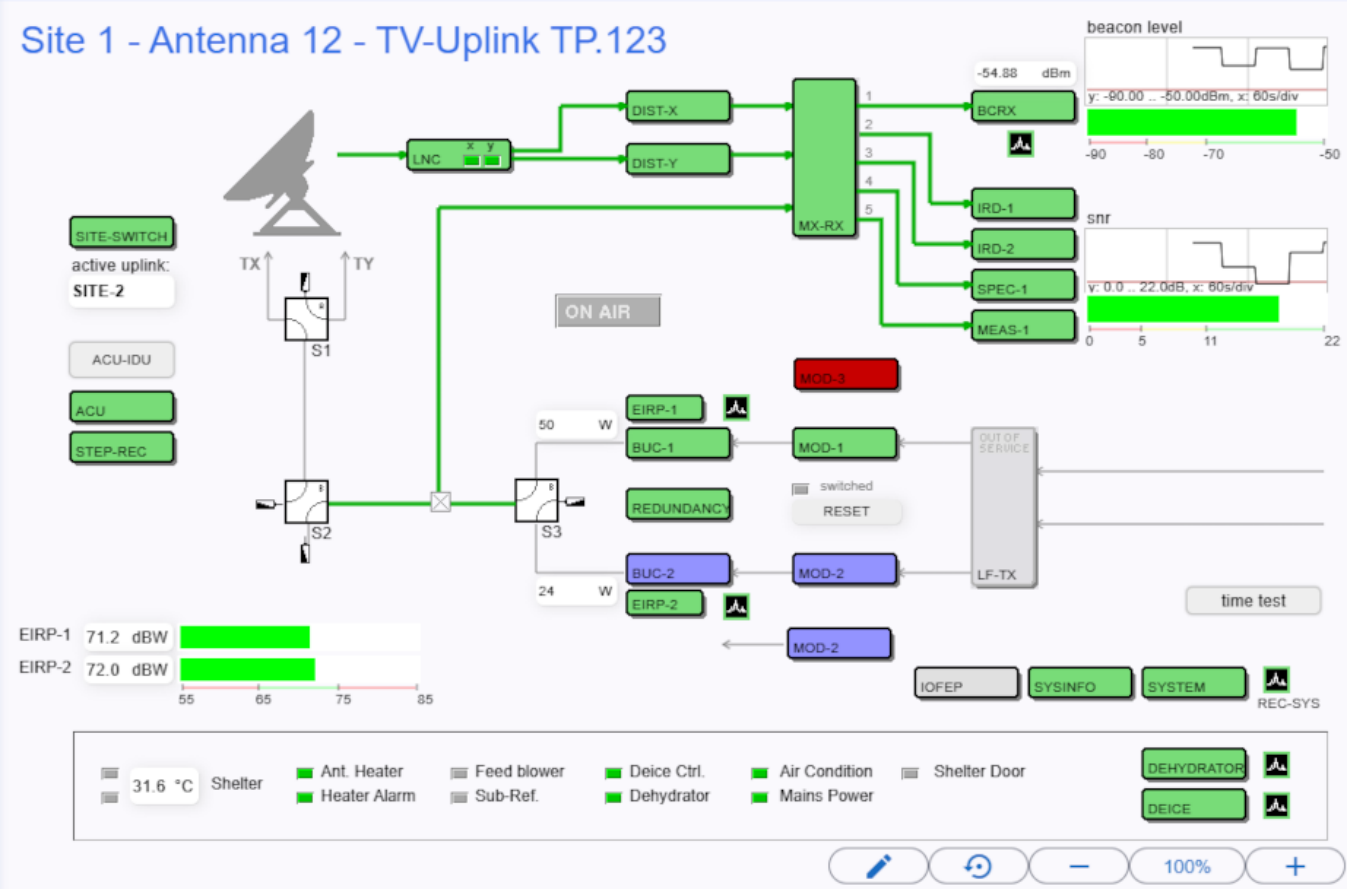
- The Main Window adapts dynamically based on the selected page or action.
- It works together with the top toolbar, the sidebar and the bottom toolbar to ensure a seamless user experience.
- Users can navigate between different sections using the sidebar menu or other navigation controls, and the content in the Main Window updates accordingly.

Following content types are shown in the Main Window:

- sidebar menus functions (expect tree view)
- user screens
- device windows
- all dialogs

2.2.1 User screens

The User Screens are the screens that are configured withthe screen editor. You can interact with the user screen (zoom in or out, scroll vertically or horizontally, reposition the entire screen) and the elements (depending on the element). You do not have to reload page to get the actual values. The values of the elements are always updated. If you move the mouse over an element, details about this element are displayed on left bottom corner of main window. However, you must activate this setting in the user settings under 'Debug mode'.



In the bottom right-hand corner of themain window there is a toolbar with the following

functions:

Function	Icon	Description
edit screen		open the screen editor with the active user screen
Reset position		resets the position of the user screen
Zoom out		zoom out, scale down the elements inside of the page
Current zoom		display the current zoom of the user screen. Clicking on it works like a button and resets the zoom to the default setting.
Zoom in		zoom in, scale up the elements inside of the page

User screens shortcuts

- **Zooming**
  - ctrl + + to zoom in.
  - ctrl + - to zoom out.
  - ctrl + 0 to rest zoom.
  - ctrl + mouse wheel to zoom in and out.
- **Scrolling**
  - Mouse wheel for vertical scroll.
  - shift + mouse wheel for horizontal scroll.
- **Drag and drop**
  - Space + hold mouse left click + mouse move to drag and drop the user screen on desired position.

2.2.2 Display elements

This section described briefly all the display elements e.g. interaction, state behavior, disable type etc. If you want to check the display element properties please check the element properties in Screen Editor chapter.

Category	Element	Readonly	Interaction	Dynamic update	Update data
Static	Text	□	□	□	□
	Frame	□	□	□	□
Dynamic non-interactive	Display (Readonly)	□	□	□	□
	Icon	□	□	□	□

Category	Element	Readonly	Interaction	Dynamic update	Update data
	Arrow	□	□	□	□
	Rect	□	□	□	□
	Gauge	□	□	□	□
	Thumbnail	□	□	□	□
Interactive	Parameter	□	□	□	□
	Parameter button	□	□	□	□
	Latching button	□	□	□	□
	Radio button	□	□	□	□
	Button	□	□	□	□
	Device icon	□	□	□	□
	Switch icon	□	□	□	□
	Chart	□	□	□	□
	XY chart	□	□	□	□
	AzEl	□	□	□	□
	Spectrum	□	□	□	□
	Target list	□	□	□	□

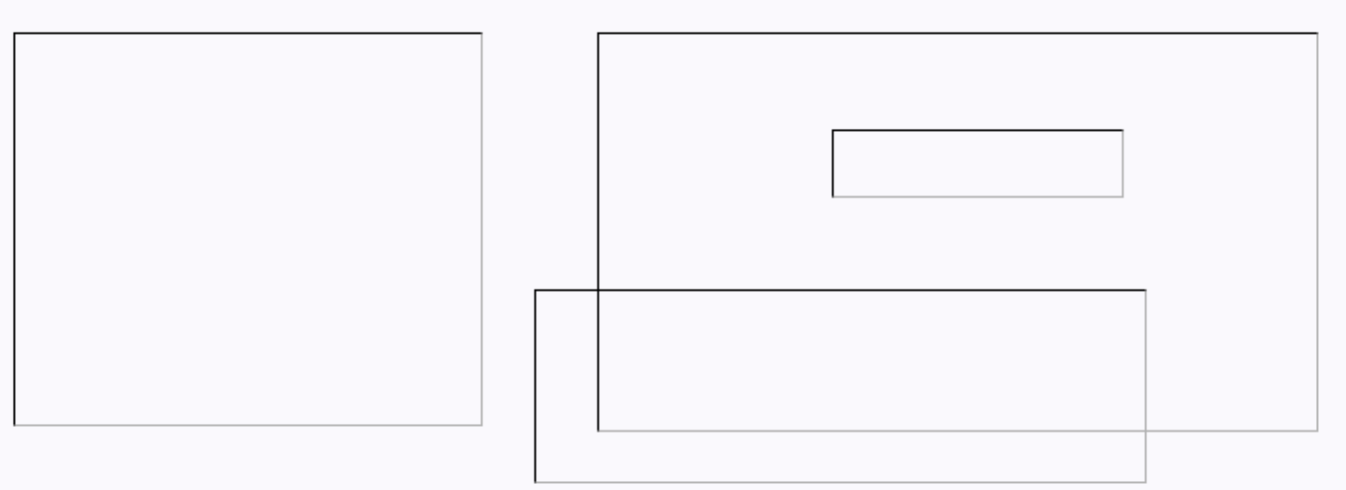
- □ : Yes
- □: No
- □: Element can be restricted with the privilege level.

2.2.2.1 Text element

The text (label) element is an static type of element and can not change their values until you changed it from Screen-Editor. It can have different color, font-style and font-size.

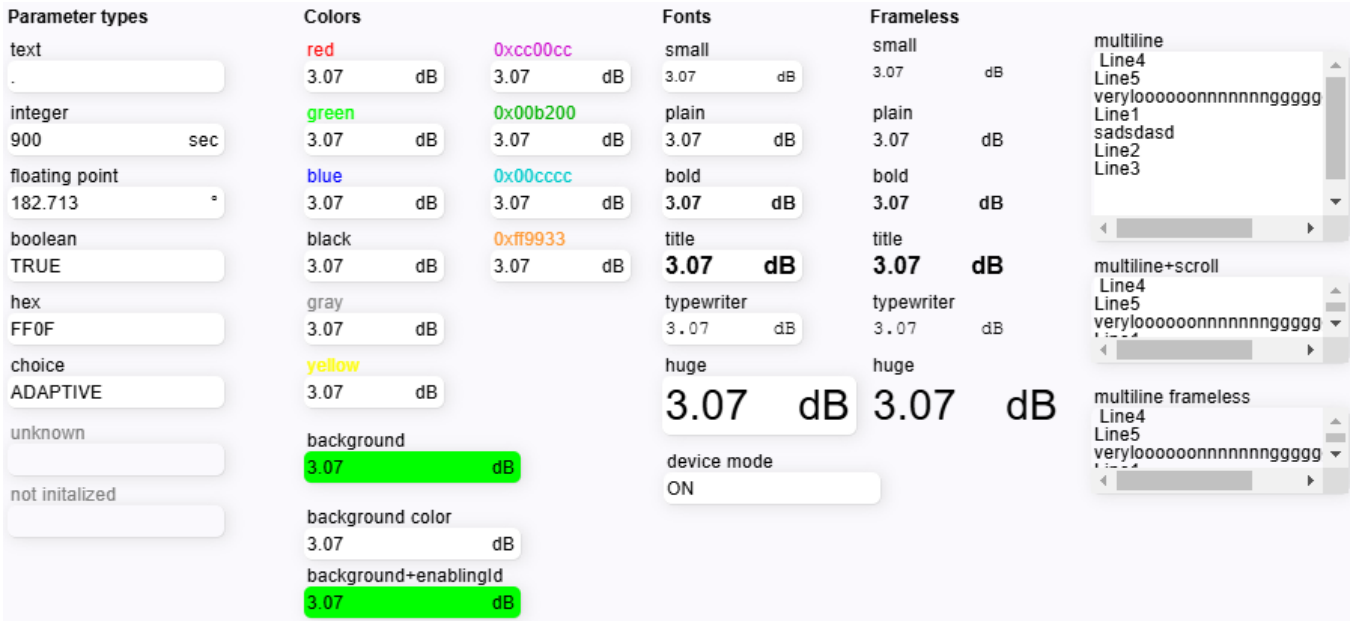
2.2.2.2 Frame element

The Frame element is an static type of element and draws a sunken 3D frame, which is intended to be used to group other elements.



2.2.2.3 Display element

This display element also called read-only element is an dynamic non-interactive element. That means you can not interact with the element to edit or send values. But it still get's updated value. This element is most like parameter element only with the difference that you can not interact with it.

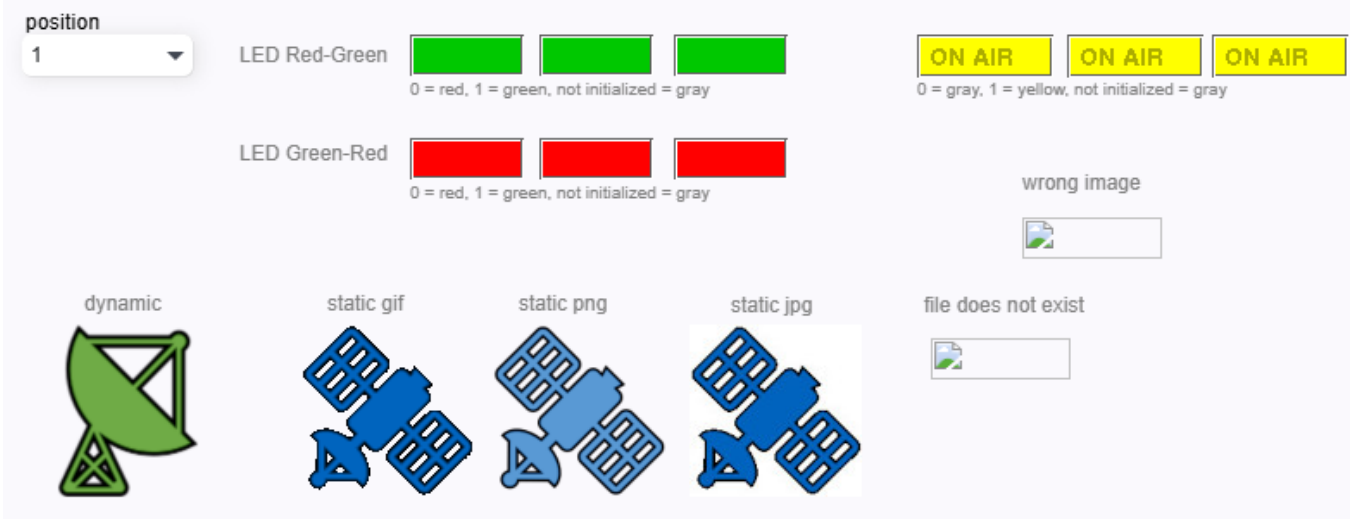


The image above shows the different types of color, fonts, types, background etc. to get an overview of possible looks of the display element (readonly element). Additional colors or background colors can be configured in the element properties in the screen editor.

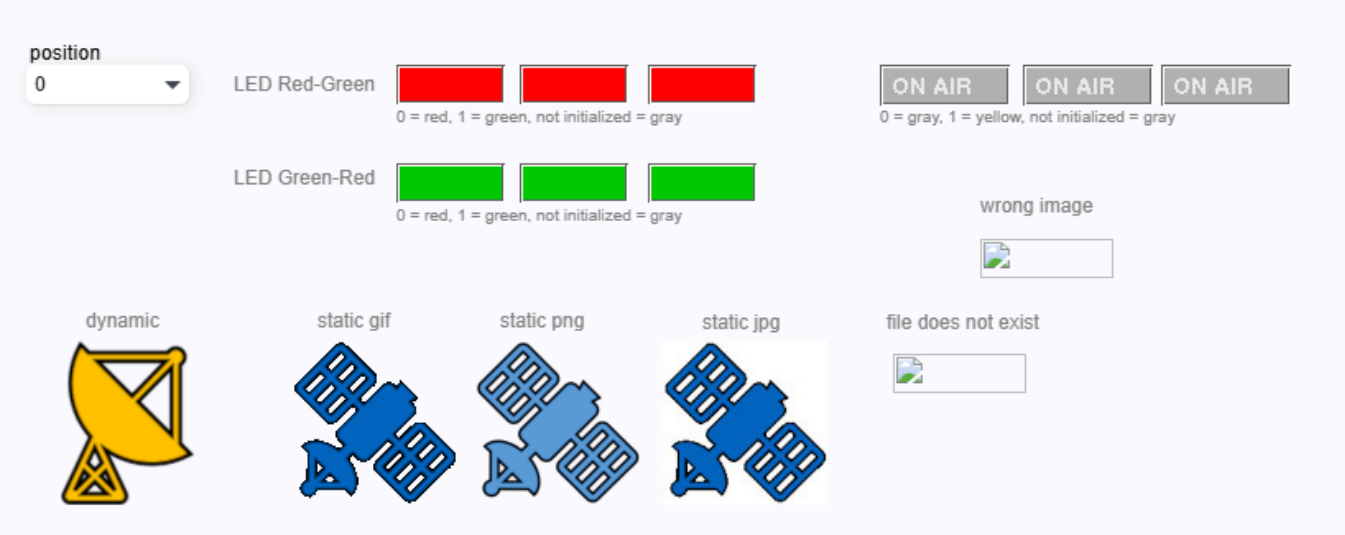
2.2.2.4 Icon element

The icon element works as a dynamic non-interactive element and also as a static element. If message ID in the element properties configured, it will works like an static element type, otherwise it works like dynamic non-interactive element.

The images below shows static and dynamic icons.



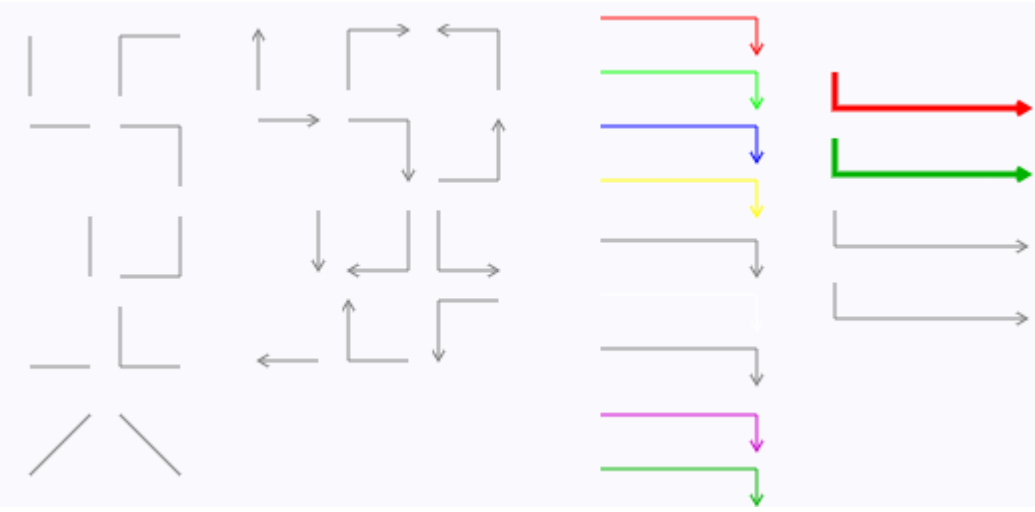
Dynamic icons are bind with position parameter element.



NOTE: Please be careful on selecting an icon with message ID. Wrong image heading in above image is better example of this. Some of the icons contain the name of 0, 1, on or off. For example in above page parameter value can be between 0 and 1. The icon will be changed to parameter value.

2.2.2.5 Arrow element

The Arrow element work as a dynamic non-interactive element and also as a static element. It draws a horizontal and/or a vertical line and optionally an arrowhead. The arrow/line's color is selectable, also may follow a parameter value. You can configure the element properties in the screen-editor.



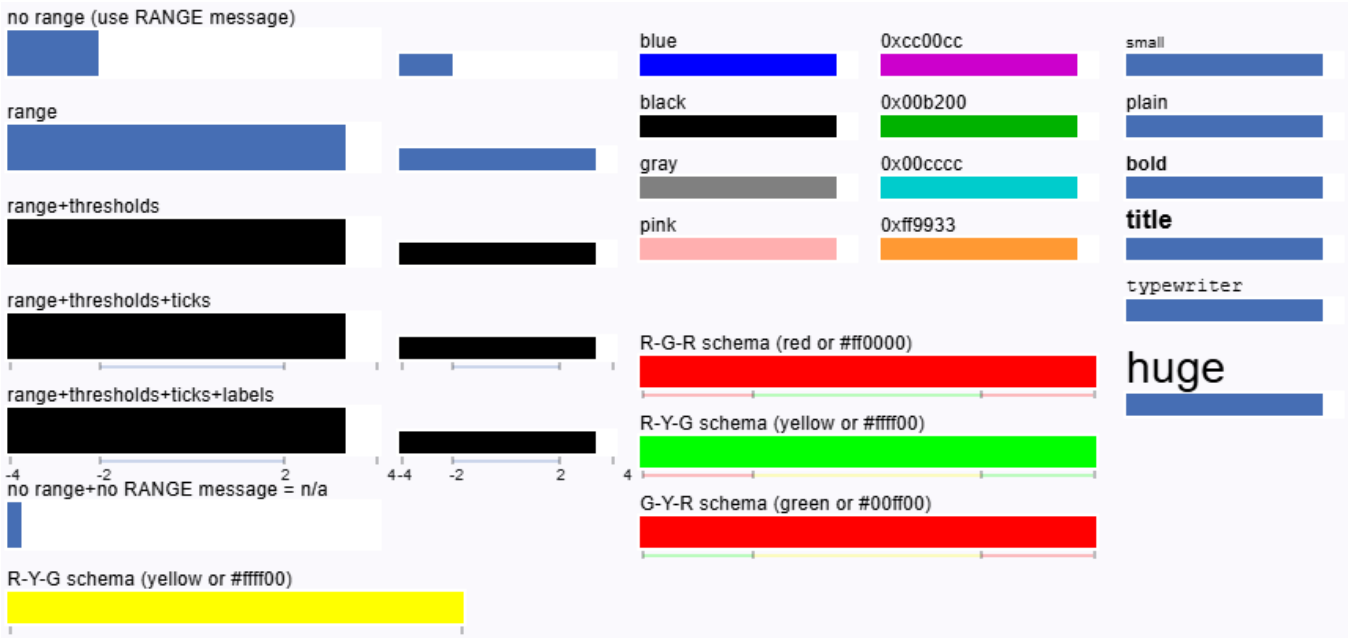
2.2.2.6 Rect element

The Arrow element work as a dynamic non-interactive element and also as a static element. It draws a rectangle with a selectable color. The element may listen to a parameter value and change the color of the rectangle according to the parameter value.

2.2.2.7 Gauge element

The gauge element is an non interactive element and shows a numeric parameter value as a horizontal bar in an entry field like frame. The gauge element is capable to adjust the scale factor for the gauge automatically from the parameter's range definition. Alternatively the scale parameters may set explicitly.

Image below shows the gauge elements with different type of element properties.

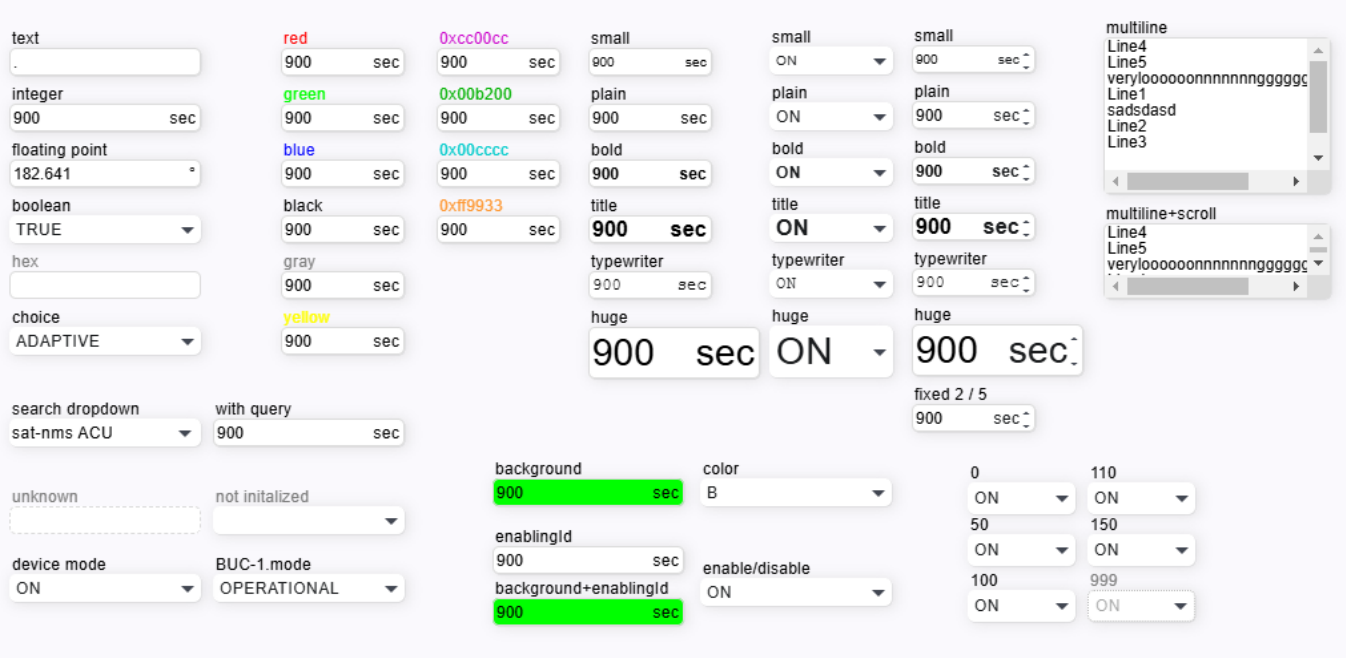


2.2.2.8 Thumbnail element

2.2.2.9 Parameter element

The ParameterElement is the common component to display and edit most types of M&C parameters. Depending on the data type of the parameter (the data type is detected automatically) the parameter elements appears as textual / numeric entry field, choice box or as display field for read only parameters.

In the image below are the all variants of parameter element.



Widget Variants: Depending on the type of parameter and on the*height* parameter there are different widget types associated with the ParameterElement. As the parameter type is not known at the time the screen definition is read, the decision what widget type shall be used must be done after the parameter type description has been received from the server.

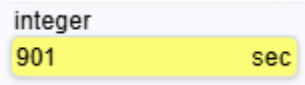
Parameter Type	***height < 40***	***height >= 40***
Text	single line entry field	multi line entry field, scrollable if text does not fit into the field
Numeric	single line entry field	single line entry field
Enum/Choice	drop down or combo box	scrollable list selection
r/o Text	single line display	multi line display, scrollable if text does not fit into the field
r/o Numeric	single line display	single line display
r/o Enum/Choice	single line display	single line display

Spin Buttons: With *useSpinButtons* set 'true', the ParameterElement shows spin buttons with editable numeric values. The spin buttons allow to increment/decrement the value by clicking on them. By default, a spin button click increments or decrements the lowest significant digit

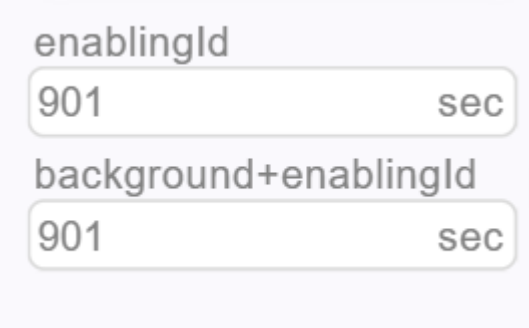
shown in the entry field. With the shift key hold down, the effective increment is x10. The above applies if the *spinSmallIncrement* / *spinLargeIncrement* properties are empty. If set, these values override the defaults.

Unsaved changes

If you have changed the value of any parameter element, the background of the input field turns yellow. As soon as you have saved the changes by pressing the Enter key or leaving the input field, the background color of the input field returns to normal.



Element disabled

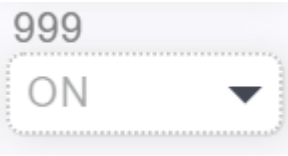


Element readonly

Readonly elements is displayed with dashed border with grey text color.

Element disabled because of low privilege level

Elements is displayed with dotted border with grey text color.



2.2.2.10 Parameter button element

The parameter button element is an interactive element and a button which sends a parameter value if pressed. A frequently used application for the parameter button is a RF-OFF button which sends a "tx.on=OFF" to a certain device. Beside this, a parameter button also may be programmed to play a parameter setting macro.

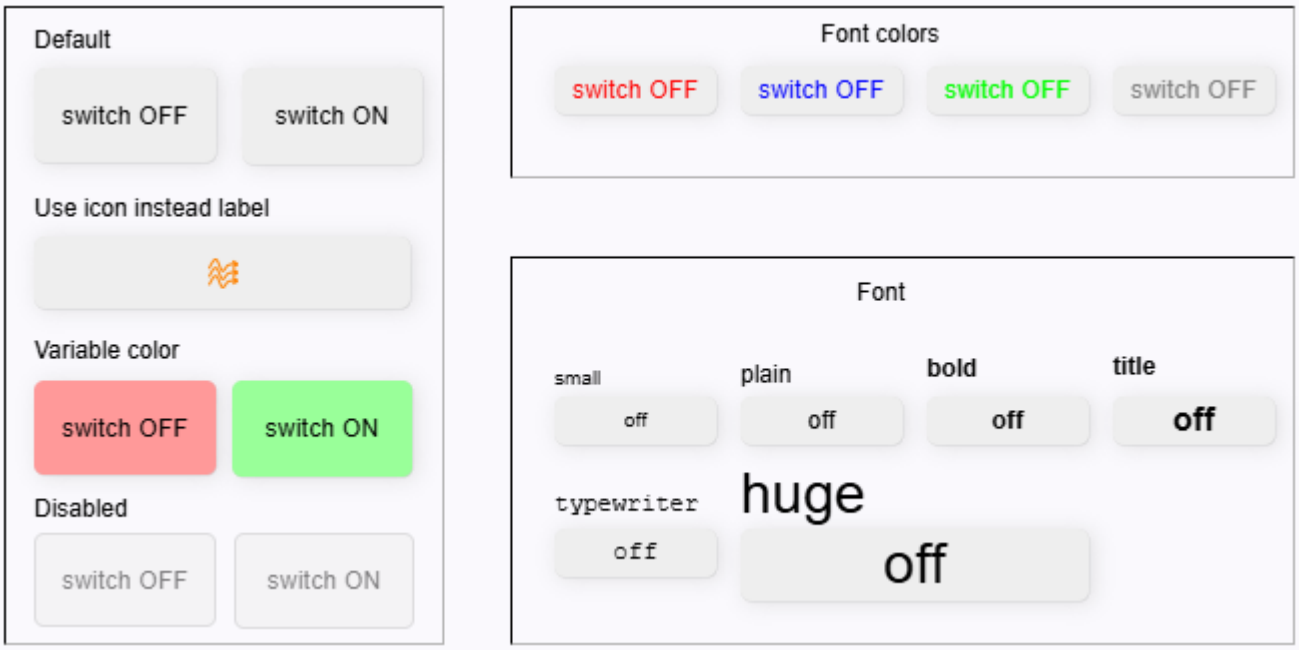
The parameter button element never uses a button label and an icon at the same time. Either

icon or label is an empty string.

If no parameter value is set, the parameter button element sends the button label or the icon name as the parameter value when clicked.

Macro Buttons

The MacroButton is a special version of the parameter button element. A*isMacroButton = true* marks a parameter button element to be a MacroButton. In this case the 'id' field contains the name of the M&C where to play the macro and the macro name in this case, separated by a period.



2.2.2.11 Latching button element

The latching button element works much like the[parameter button element](#) described earlier in this document, but is specialized to show and control an enumeration parameter which knows exactly two states (e.g. on/off or true/false).

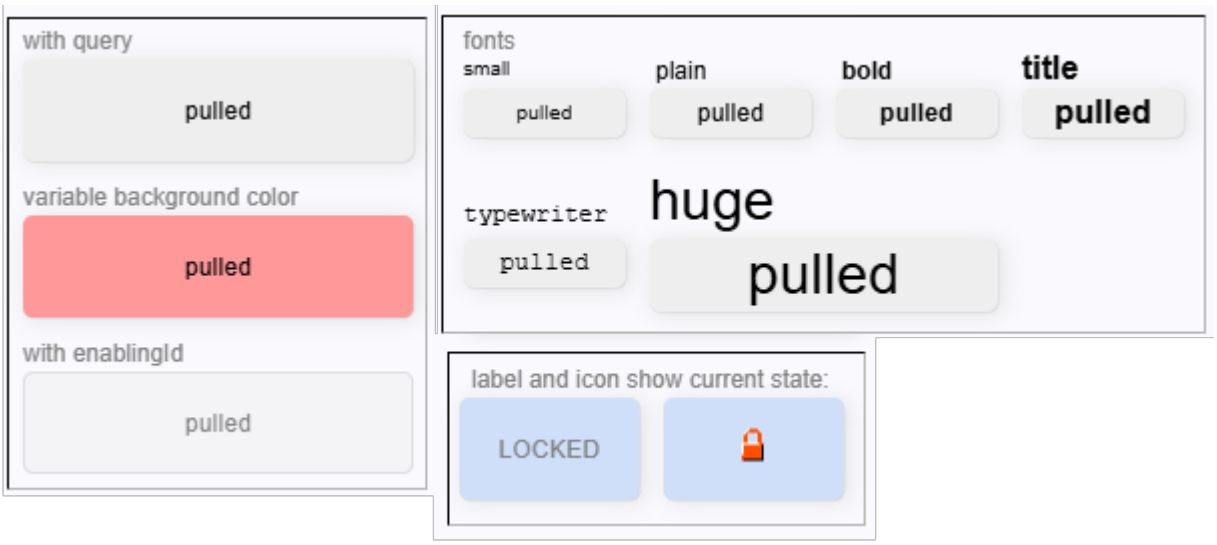
When the operator changes the state of the button by clicking it once, the latching button sends the 'other' parameter value to the device. On the other hand, if some other instance in the system changes the parameter state, the latching button recognizes this and changes the up/down state of the button accordingly.

Like the parameter button, the latching button may be labeled with text or an image. To reflect the actual state, the latching button always is configured with two text string or two image names which are shown according to the actual parameter value.

The latching button element never uses a button label and an icon at the same time. Either iconUp / iconDown or labelUp / labelDown contain empty strings.

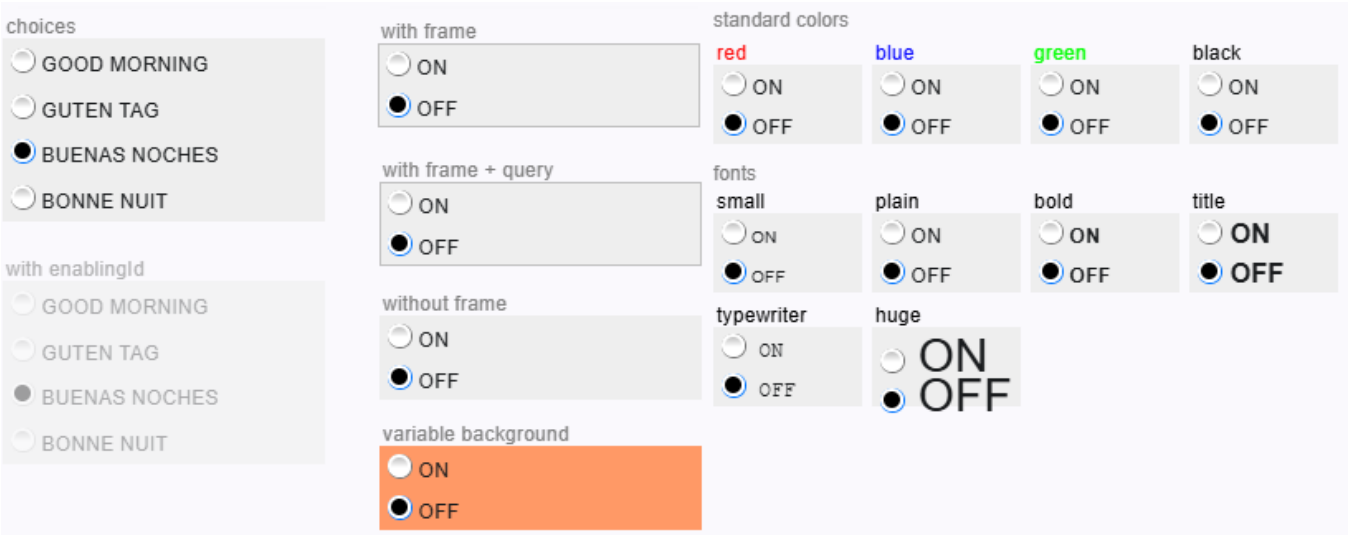
The valueUp and valueDown values are not only sent when the button is pressed or released.

They also are used to set the button state when a parameter value is received though id: If the value matches valueDown the button goes to 'pressed' state, in all other cases the button gets released. Labels or icons change an this moment according to the new state.



2.2.2.12 Radio button element

The radio button element is a component to display and edit CHOICE type M&C parameters as a number of radio buttons. Depending on the height of the element, radio buttons are positioned in a row or in a column (height<=40 means position horizontally). The radio buttons are labeled with the choices of the parameter, there are as many radio buttons as choices in the parameter range.



2.2.2.13 Button element

The button element creates a button which launches another user interface screen if pressed. The screen to be launched may be another user defined screen or a predefined one.

The *action* field of the ButtonElement defines what the button will do when clicked by the operator. The list below shows all known values for *action*, the meaning of this and a description of the parameters *par1* and *par2* which will have different meanings for particular action.

CHILD-SCREEN

Launches a new browser tab or window showing the user screen referenced with*par1*.

- *par1:* The name of the user screen to show.
- *par2:* null
- *par3:* null

REPLACE-SCREEN

Replaces the actual user screen by the one referenced with*par1*.

- *par1:* The name of the user screen to show.
- *par2:* null
- *par3:* null

LOAD-PRESET

Launches a "Load Preset" dialog which lets the operator select and apply a device preset from a list of presets which are defined for this particular type of device. Device presets are local to each M&C instance, have to be loaded and applied from there.

- *par1:* The name of the device to which the preset shall be applied to. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MYDEVICE` (must be set in the screen editor this way).
- *par2:* The name of the driver of this device.
- *par3:* An option search pattern to filter the list of displayed presets. All presets containing the given string (not case sensitive compare) shall be shown. If *par3* is null, all preset for the given device / driver combination shall be shown.

FREC-VIEW

Launches a File-Recorder view window. This window shows the data recorded by the File-Recorder device referenced with *par1* or the live data provided by this device.

- *par1:* The name of the File-Recorder device. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MY-FREC` (must be set in the screen editor this way). In the device screen of the file recorder, the special device name "." denotes *this* device.
- *par2:* The file recorder view preset number (0..7) to be applied. May be null, in this case no stored settings are applied.
- *par3:* null

SPECTR-VIEW

Launches a Spectrum Display window. This window in fact is a device screen of the CSM-Spectrum-Analyzer device.

- *par1:* The name of the spectrum analyzer device. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MY-FREC` (must be set in the screen editor this way).
- *par2:* A comma separated list of message-id/value pairs. Within each pair the message-id is separated from the value by one space character. Message ids are fully qualified, starting with the M&C name (must be set in the screen editor this way). The Spectrum Display window shall parse this list and send every message defined in the list with a poke call to the backend. This macro-like function is used to initialize the spectrum analyzer or to switch its input when the window is launched.
- *par3:* null

BROWSER-VIEW

Opens a new Browser window and displays a given URL in this window. This function is used to invoke the sat-nms online help and to launch the Web-GUI of certain devices.

- *par1:* The URL to show. Before launching the browser window, some replacements have to be done on the URL string:
  - If *par1* is a string consisting only of 4 decimal digits, this is a sat-nms online help topic number and the string must be expanded to the full URL from where this topic can be loaded by the browser.
  - If the ButtonElement is part of a device screen and the URL contains '@' characters, they have to be replaced with the (IP-) address of the device. A double '@@' escapes this behavior and gets replaced by a single '@' in the URL string.
- *par2:* null
- *par3:* null

TREE-NAVIGATE

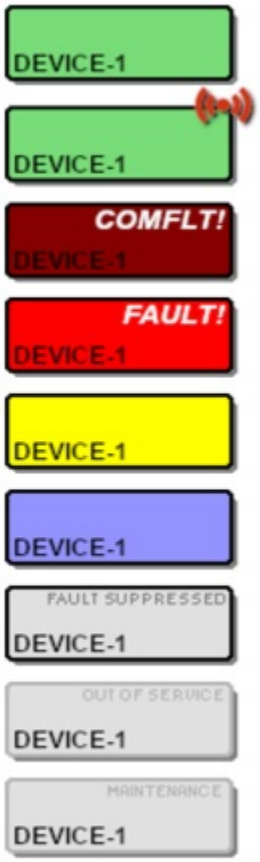
In a tree view UI this button navigates in the tree to the tree path referenced with *par1*. As the tree view UI with the WebUI is still t.b.d., this description should be considered as preliminary.

- *par1:* The tree view path to navigate to.
- *par2:* null
- *par3:* null

2.2.2.14 Device element

The device icon display element represents a device in the M&C user interface. It displays the status of the device by it's color/shape and gives access to the device details panel panel for this particular device by a mouse click.

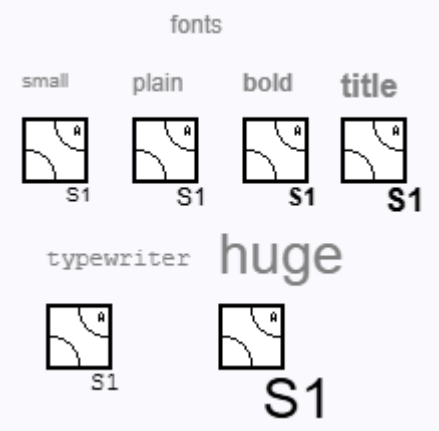
- Operational – ok
  - Device polling active, no alarm/fault
- Operational – ok, transmitting
  - Operational + ok and TX on
- Operational – CommFlt
  - No response from equipment
- Operational – fault
  - Device polling active, alarm/fault active
- Operational – warning
  - Device polling active, warning active
- Redundant unit
  - Operational + ok, Standby unit in a redundancy setup
- Fault-Suppressed
  - Device polling active, faults will be ignored
- Out-Of-Service
  - No polling, no controlling possible
- Maintenance
  - No polling, no controlling possible



(User defined device icons set with different color schemes are available)

2.2.2.15 Switch element

The switch element is a special version of the device element which may be used to visualize the position of a switch in a user interface screen designed as a block diagram. The switch icon has all capabilities of a plain device icon display element. The device details panel opens an you can toggle the position of switch.



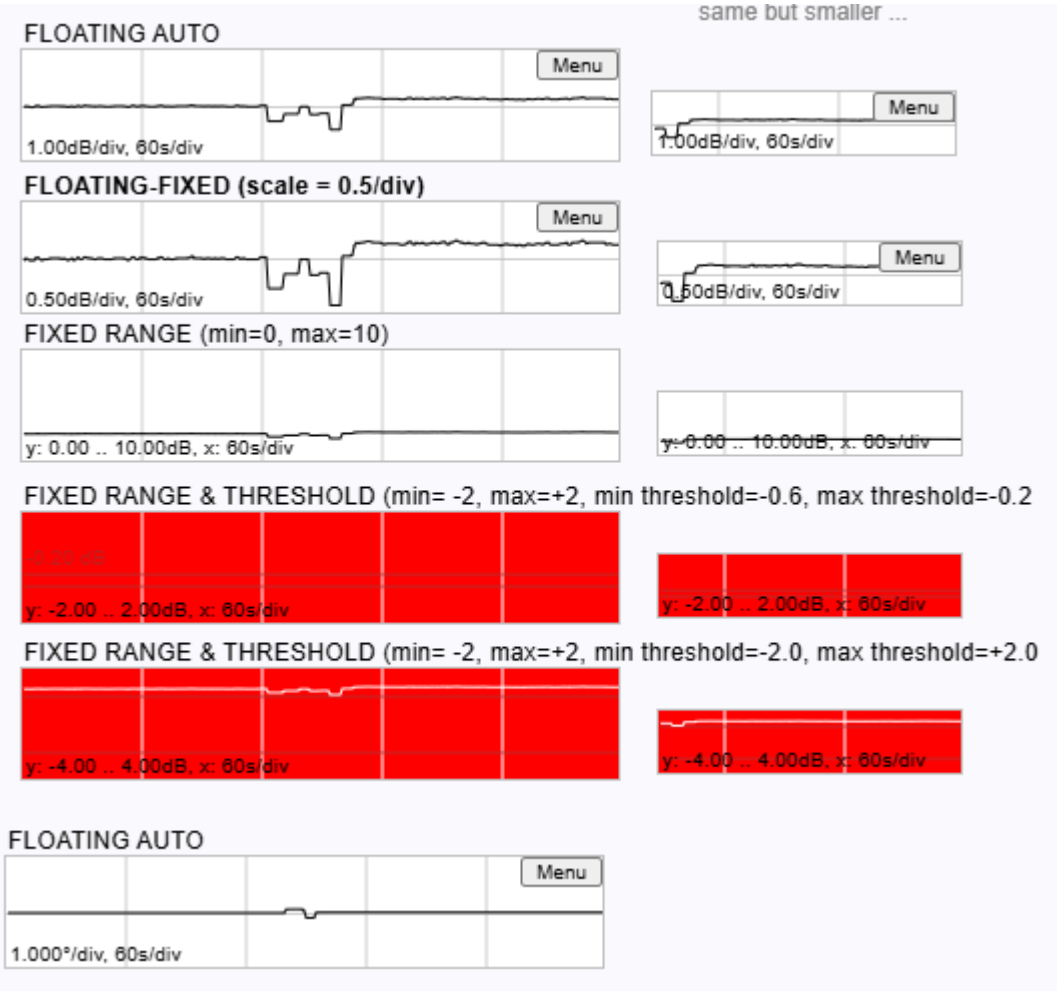
Icon Selection

The switch element displays one icon of a given set depending on the switch position and the state of the switch device. For this the SwitchElement appends a '-' character, a 2-character status code and the suffix '.png' to the icon name given in *icon* in order to ge the file name to load / display:

2.2.2.16 Chart element

The chart element shows a strip chart of a numeric parameter. The chart element keeps a local history of the received values, advances with a constant speed of 1 pixel / second. The default y-scale is 1/division but may be changed by clicking to the chart with the right mouse button.

By default, the strip chart element lets the y-scale offset follow the displayed value that the recent measurement samples are shown in the diagram. This behavior is optimized for applications where the strip chart shall indicate a 'trend' for the displayed value, using an element height of only 50 pixels or less.



Display Modes

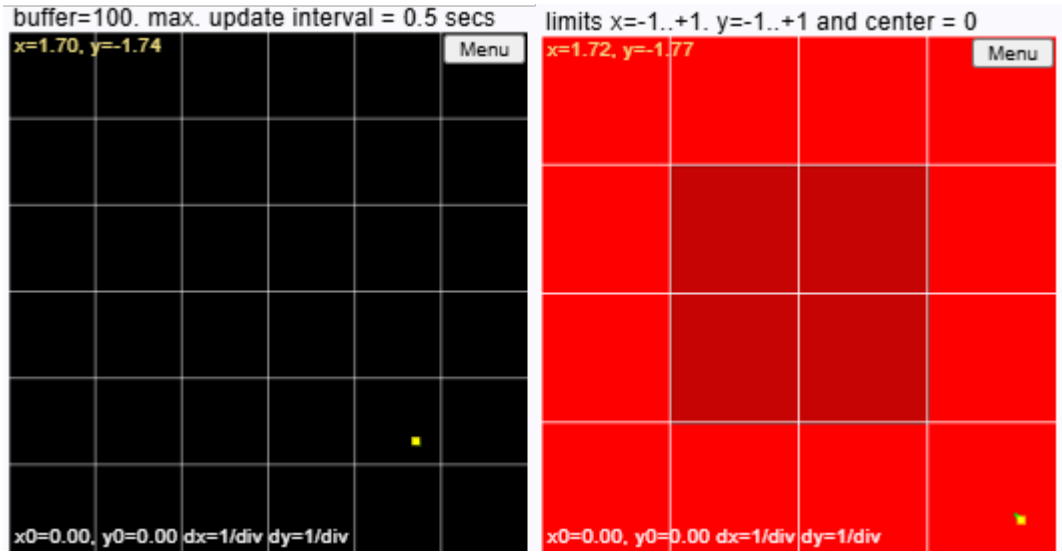
The ChartElement uses different display and scaling modes, depending on the display mode defined in *mode*. The table below lists the defined display modes an their behavior.

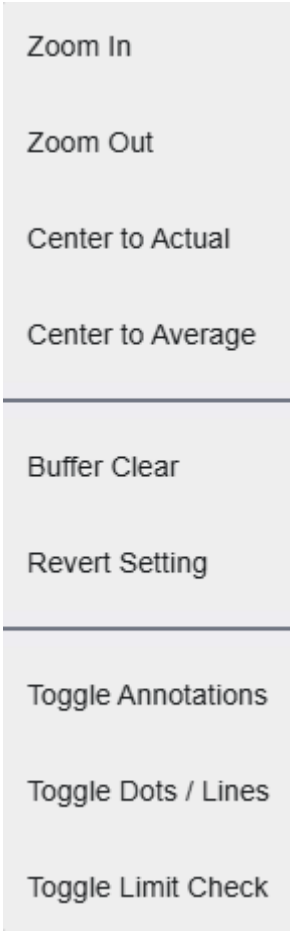
mode	**Description**
FLOATING-AUTO	Does a full autoscale. The y-offset of the strip chart is set that the newest value displayed appers at the middle of the y axis. The chart y-scale is evaluated in a 1-2-5 raster to the finest scale that allows all points in the history to be displayed in the chart area. All scaling parameters are ignored.
FLOATING-FIXED	Evaluates the y-offset like in **FLOATING-AUTO**, but applies a fixed y-scale as defined in *scale*. The *scale* value is 1/div and chart height is assumed as 2 divisions. So, the top line of the chart corresponds to y-offset + *scale*, the bottom line to y-offset -*scale*.
FIXED	Sets a fixed y-range from the *minValue* / *maxValue* parameters.

mode	**Description**
FIXED-THRESHOLD	Like **FIXED**, but also checks every new value against the *minThreshold* / *maxThreshold* limits. If outside the limits, the chart background turns to red.

2.2.2.17 XY chart element

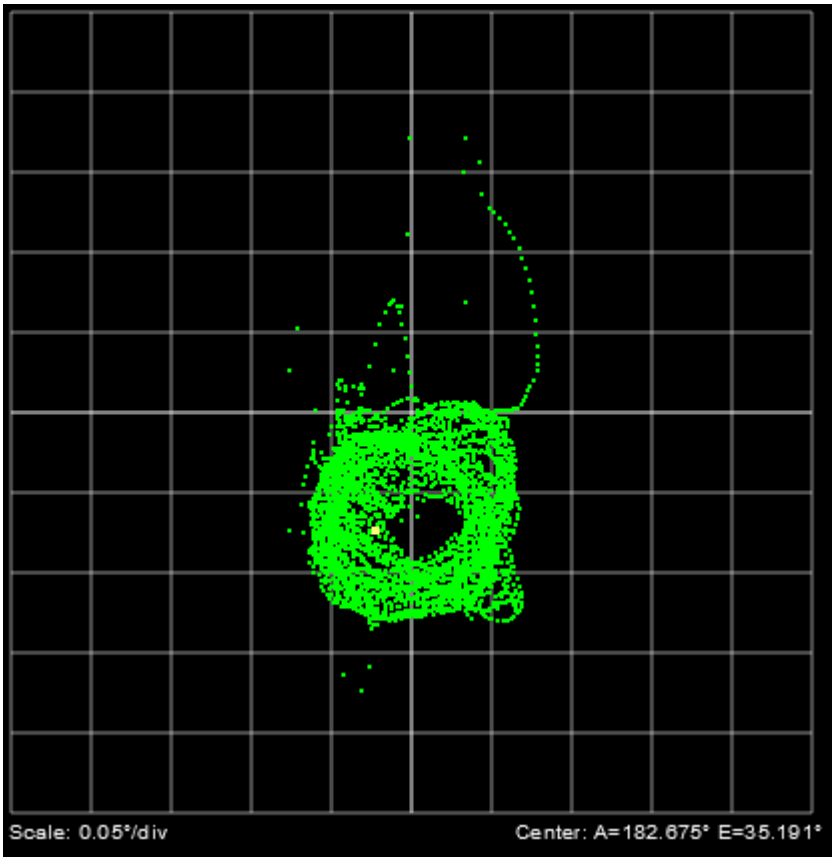
This element shows the relation of two numeric variables in an X/Y diagram, featuring a 'trace' which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.



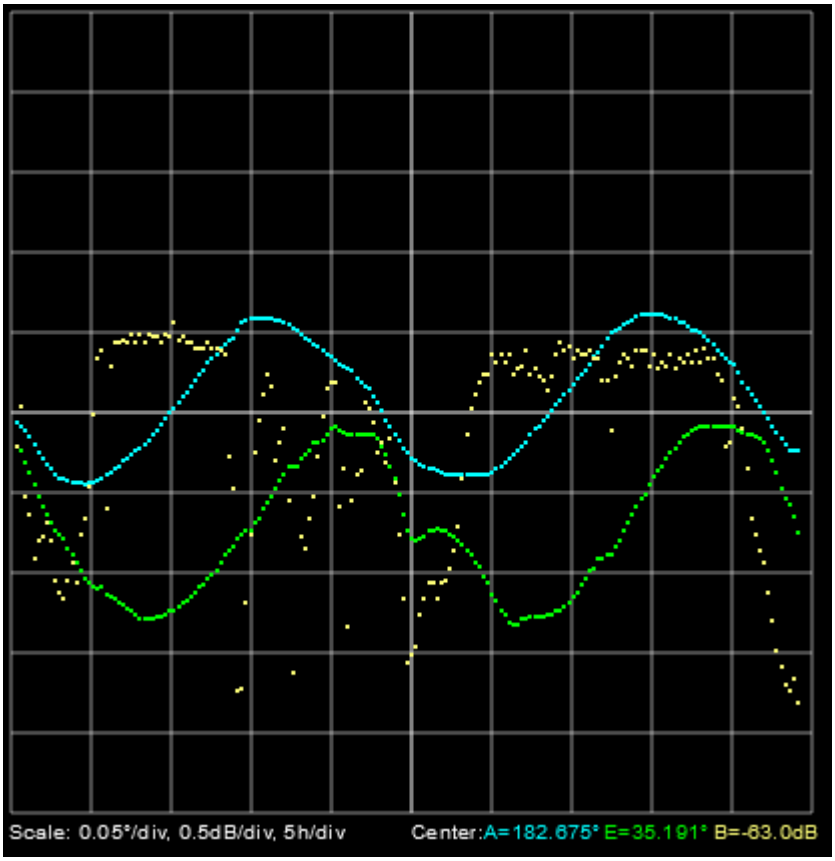


2.2.2.18 AzEl element

The AzElElement shows the tracking history of an antenna controller as a cloud of points in a elevation over azimuth coordinate system. Actually only SatService antenna controllers provide the tracking history data for this screen element.



Scale: 0.05°/div
Center: A=182.675° E=35.191°



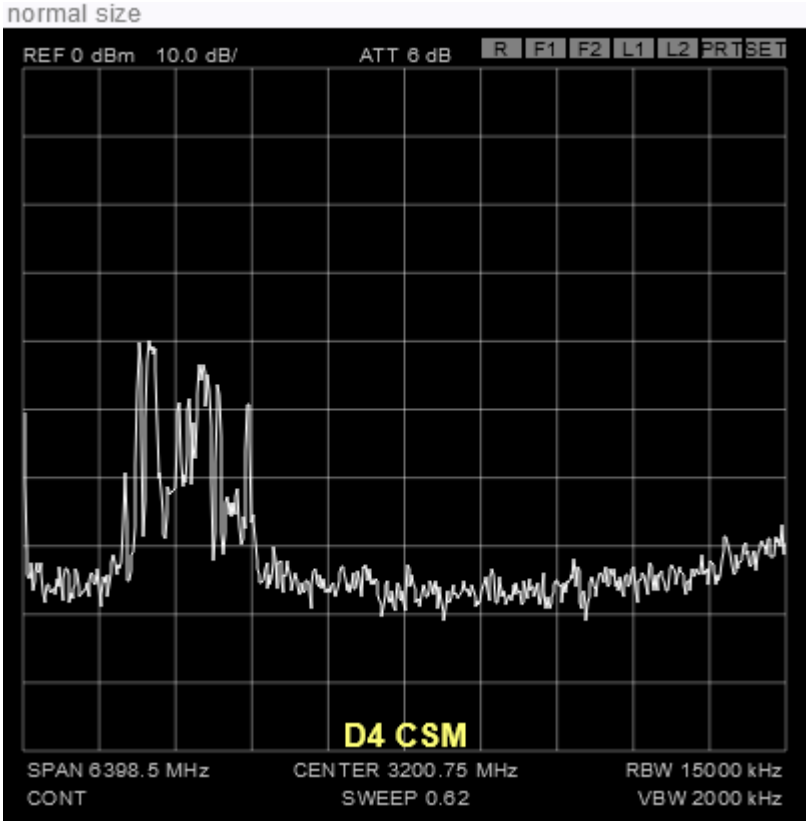
Scale: 0.05°/div, 0.5dB/div, 5h/div
Center:A=182.675° E=35.191° B=-63.0dB

2.2.2.19 Spectrum element

The spectrum element embeds the spectrum display of a spectrum analyzer device in the screen. Actually, only the CSM-Spectrum-Analyzer device may be used with the spectrum element.

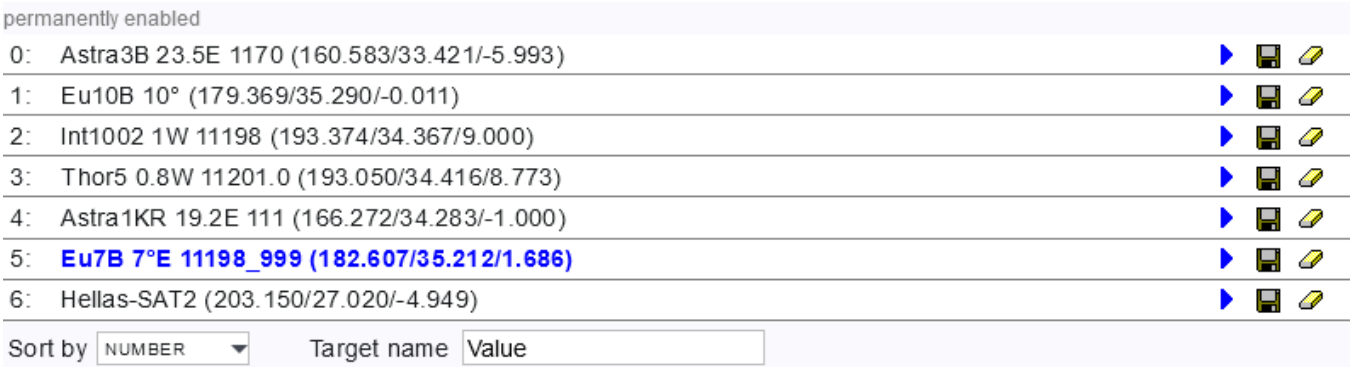
The spectrum element subscribes for a variety of parameter of the spectrum analyzer device to display its settings in the diagram area. It also permits to command some aspects of the spectrum analyzer device like the marker position. The spectrum data itself is read by subscribing for the 'trace' parameter of the device. This returns the spectrum data as a SpectrumTrace with each sweep of the spectrum analyzer. A complete description of the function of the spectrum element is given in a separate document.

normal size



2.2.2.20 Target list element

The target list element embeds the list of targets of a SatService-ACU-ODM antenna controller in the screen. Targets may be recalled (which moves the antenna to the stored position and sets the tracking parameters associated with this target), saved or deleted.



Device Name Indirection

The *id* parameter is interpreted differently depending on the context where the ODM Target List screen element resides:

- When placed in a user defined screen or in the main screen of the application, *id* is the name of the ODM device it shall refer to.
- When placed in the device screen of another device which defines a configuration variable with the antenna controller's device name, *id* is the name of this configuration variable and the name of the ODM device is derived from the content of this variable.
- Finally, when used in the device screen of the ODM device itself, *id* is '@'.

Target List Parsing

The target list element gets its information from a parameter 'target.list' the ODM device provides for this purpose. This variable contains the target list as a one line string with the target definitions appearing at fixed character positions.

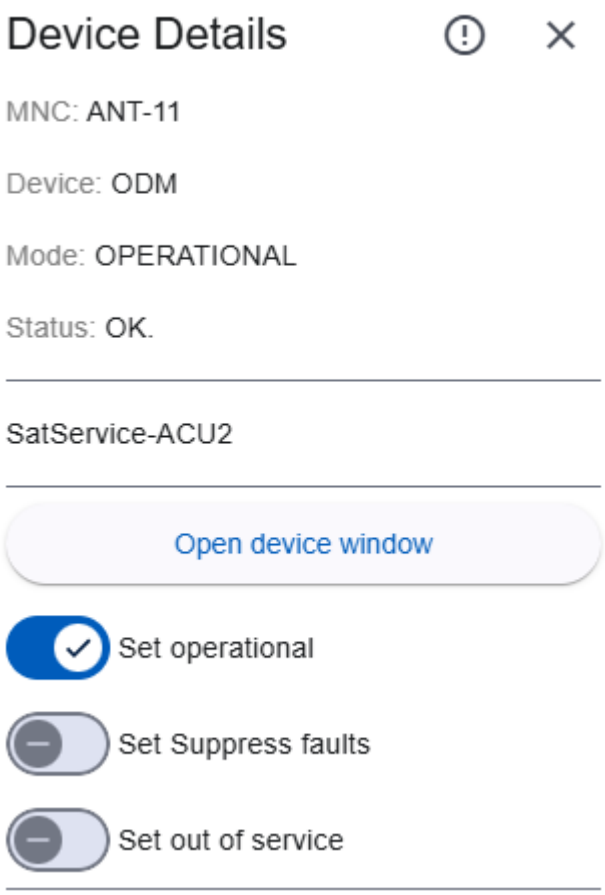
Each target definition contains the target name and the azimuth / elevation / polarization angles. The target number is defined implicitly from the position of the target in the complete string. The format of each target definition is as follows:

```
target name (azimuth/elevation/polarization)
```

This string is padded with spaces to 45 characters length. With target numbers starting at 0, you can access a particular target in the string at position *n*45* with a length of 45 characters.

2.2.3 Device details panel

The device details panel shows you the device information for a device. It is displayed on the right-hand side of the window on clicking e.g. on display element device icon. You can also perform some quick actions here, e.g. put the device into operational or out of service mode.



This panel will open if:

- click on switch icon from main screen
- clicking device in the treeview
- selecting a device from the notification panel
- selection a device from the device list page

In the title of this panel the following icons are available:

icon	description
	Click opens directly the fault page of the device. If there is any fault or warning the icon color will be red (alarm or fault) or yellow (warning) otherwise it will be gray.
	Close the device panel. You can also click outside the panel to close the panel.

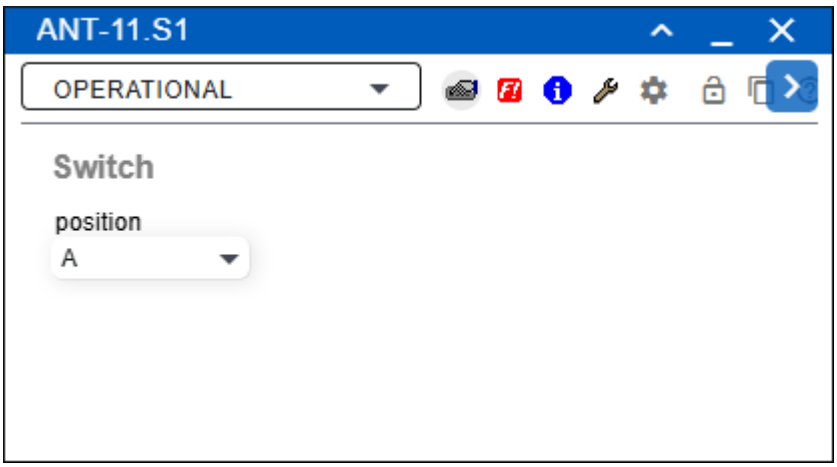
Details

- **MNC**: name of MNC where the device belongs to
- **Device**: name of the device
- **Mode**: current operations mode of the device
- **Status**: Current summary status of the device (`MNC.DEVICE.fault`)

    - **NO.**: No fault
    - **Summary FAULT**: text displayed in red color.
    - **WARNING**: text displayed in yellow color.
- **Driver name**: name of the device driver
- **Comment**: shows the device comment if set in the device config page and available for this kind of driver (`MNC.DEVICE.config.deviceComment`)
- **On Air state** shows `ON AIR` if the a devices provides this information (`MNC.DEVICE.info.signal.on`)
- **Open device window**: open device window for the device
- **Change mode switches**: change the operation mode, select between
    - OPERATIONAL: enable communcation between MNC and equipment
    - FAULT-SUPPRESSED: suppresses summary fault or warning, but stays operational
    - OUT-OF-SERVICE: disables the communication between MNC and equipment
    - MAINTENANCE: disables the communication between MNC and equipment and marks the device to be in maintenance. This triggers the inventory system if enabled.
- **Toggle switch**: If the selected device is a switch element, a toggle button is displayed. You can toggle the position of the switch `A -> B` or `B -> A`

2.3 Device window

The M&C offers a device window for each type of equipment it supports. Device windows can be launched by device details panel, device list. It shows all parameters read from the device and permits to alter each writable parameter. For clearance, the parameters are grouped to pages, you can switch between the pages using the tool-bar.



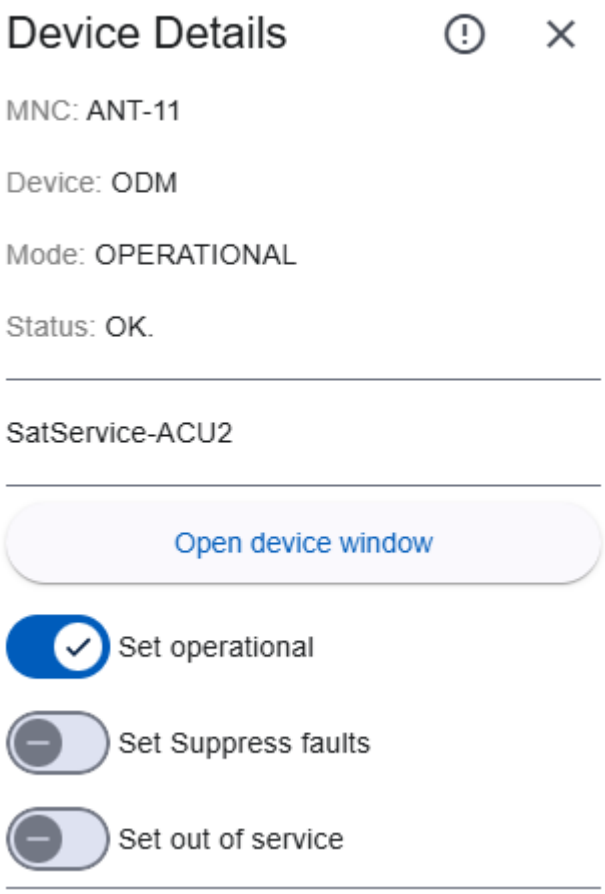
Functionality

- **Drag and drop**: Device window can be dragged from header and dropped anywhere in browser window.
- **Resize device window**: You can resize the window from every side expect top and top corners.
- **Scroll buttons**: If the toolbar menu is larger than the device window, the scroll button is displayed on the right or left side, depending on where the content is hidden.

- **Duplicate window**: The same device window can also be duplicated, which means it could be opened more the one time.
- **Debug info**: On mouse hover element details are displayed on bottom left side corner. It should be activated from 'User setting'
- **Navigates through pages**: Different type of page can be open from toolbar. Details of device window are described under 'Device window'.

2.3.1 Device details panel

The device details panel shows you the device information for a device. It is displayed on the right-hand side of the window on clicking e.g. on display element device icon. You can also perform some quick actions here, e.g. put the device into operational or out of service mode.



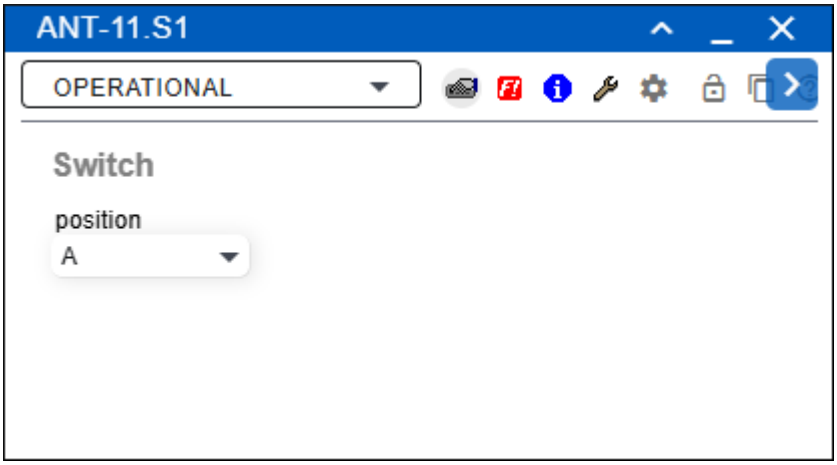
Top

- **Device details**: Title of the panel.
- **Info icon**: On click it opens a device window directly by Faults page. If there is any fault or warning the icon color will be red (alarm or fault) or yellow (warning) otherwise it will be black.
- **Close**: Close the device panel. You can also click outside the panel to close the panel.

Details

- **MNC**: The MNC name of the device.
- **Device**: The name of the device.
- **Mode**: Current mode of the device.
- **Status**: Current status (fault) of the device. "MNC.Devicename.fault" is used in this case.
  - **NO.**: No fault
  - **Summary FAULT**: Text displayed in red color.
  - **WARNING**: Text displayed in yellow color.
- **Device comment**: A device comment saved the device.
- **Open device window**: Open device window for the device.
- **Change mode switches**: By clicking on the mode set the device to the selected mode.
- **Toggle switch**: If the selected device is a display switch element, a toggle button is displayed. You can toggle the position of the switch (A -> B or B -> A)

2.3.2 Device window



The device window is a floating window, i.e. you can drag it from the header and drop it anywhere in the browser window. It has 3 main components:

Header

If the color of the header is blue, as shown in the image above, the device has no errors. If the device has an fault, the fault description (fault, warning, etc.) is displayed next to the header title and the background color of the header is also changed according to the fault (dark red on fault value "UNDEF!" and "COMFLT!", yellow on "Summary FAULT" and light red on "FAULT").

- **Title**: MNC name and device name of the device is displayed on right side of device window.
- **Roll up or down**: It roll up or down the window.
- **Minimize or Maximize window**: It minimizes the window in the bottom right-hand corner of the browser window and if window is minimized it maximizes the window to the last known position.
- **Close**: Close the device window.

Toolbar: Various devices have different options for the toolbar, but most have the common options.

- **Mode selector dropdown**: The operation mode selector displays and sets the device operation mode. Device operation modes are:
  - **OPERATIONAL**: This is the normal operation mode.
  - **FAULT-SUPPRESSED**: The M&C server normally polls and controls the device, but does not generate a device summary fault if the is a fault condition with this unit.
  - **OUT-OF-SERVICE** The M&C server does not try to communicate with the device at all. If you alter parameters of a device in this mode, this has no effect.
- : Opens a Load Device Preset dialog which lets you select a formerly stored device preset and apply the stored setting to the device. The chapter 'Preset editor' gives more information about device presets and how to handle them.
- : Click on *save* icon opens a Store Device Preset dialog which lets you store the actual device settings at the server for later retrieval.
- : Switches the window to the 'faults' page. This page displays all fault flags the software knows about this device.
- : Switches the window to the 'info' page. This page gives some information about the type of equipment controlled.
- : Switches the window to the 'maintenance' page. This page lets you set some configuration parameters and gives access to the 'low level interface' of the device.
- : Config page can be open by *settings* icon from toolbar.
- : Locks the operation of the device (through lock icon) that no other user can change device settings. See paragraph device locking below for details. If locked, the button shows a red lock.
- : Duplicates / clones this window. This is useful if you want to have more than one instance of a device window open at a time.
- **Help**: Launches the web browser with the help page for this individual device type. For a list of device types supported by the software see the 'Device Driver Reference'.

Device locking

Clicking the *settings* icon button once locks the operation of the device. The button icon changes it's color to red . If the device is locked, no other user may change devices settings. Locking is done along the user name, hence if you are logged in a second time an another place, you can operate the device from there as well.

A second click to the lock button releases the lock. Only the operator who set the lock may release it. This need not to be done at the same place where the lock was set bot you must be logged in with the same user name.

Administrators (with a privilege level of 150 or above) may release the lock in any case, also a restart of the sat-nms M&C server releases all pending device locks.

Content

Writable parameters are shown below the toolbar, read only parameters appear with the standard gray background of the window. Choice parameters are changed immediately when you alter the selection. If you edit a text parameter, the field is shown with a yellow background. Once you press ENTER or you leave the field, the changed value gets transferred

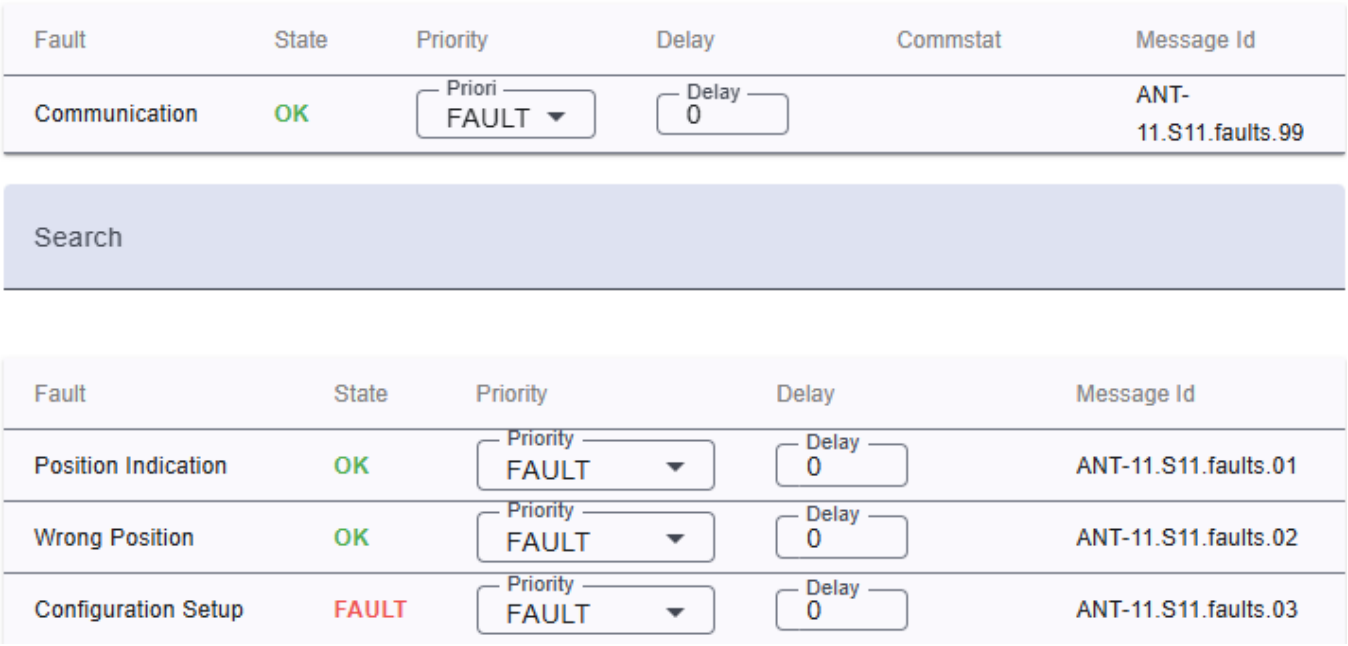
to the device. To cancel a parameter setting press ESC. The old value gets restored in the field and the background color returns to light gray. No parameter value is sent to the device in this case.

2.3.2.1 Device window pages

For a list of device types supported by the software see the'Device Driver Reference'.

- Fault page
- Info page
- Maintenance page
- Config page

2.3.2.1.1 Fault page



Moreover, you can view and change the event priority for each particular fault flag:

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

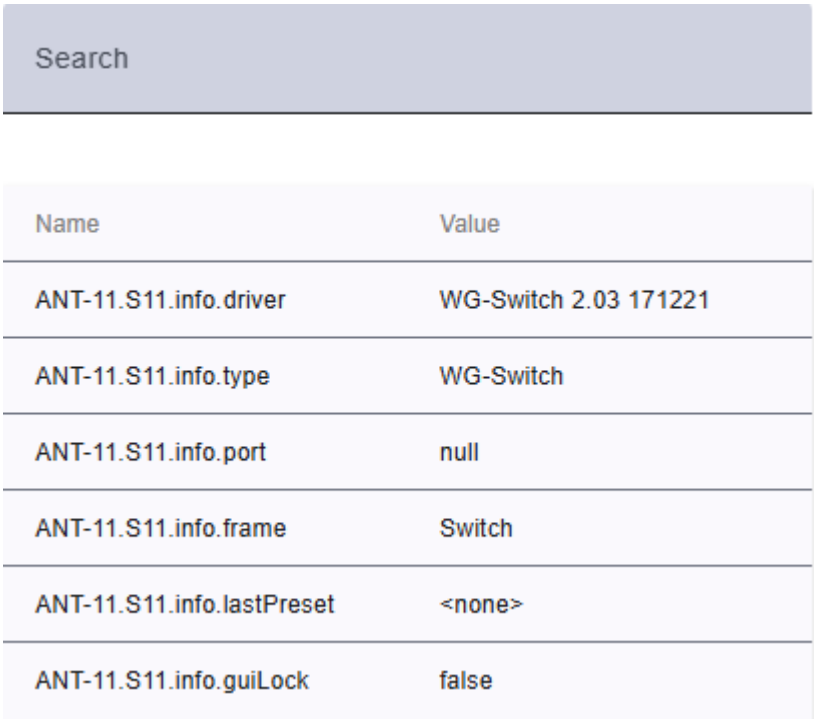
- **Fault**: The name of the fault.
- **State**: State or fault of device.
- **Priority**: Priority of the fault.
  - **OFF**: This flag is completely suppressed.

    - **INFO**: This flag is signaled as an 'informational' event.
    - **WARNING**: This flag is signaled as a 'warning' event.
    - **FAULT**: This flag is signaled as a 'fault' event.
    - **ALARM**: This flag is signaled as an 'alarm' event.
- **Delay**: Delay on trigger alarm.
- **Commstat**: (Communication status) shows if the description of fault.
- **Message id**: Message id or fault flags.

Search bar: Allows users to filter events by keywords.

2.3.2.1.2 Info page

This page gives information about the device. It is readonly page.



Search bar: Allows users to filter events by keywords.

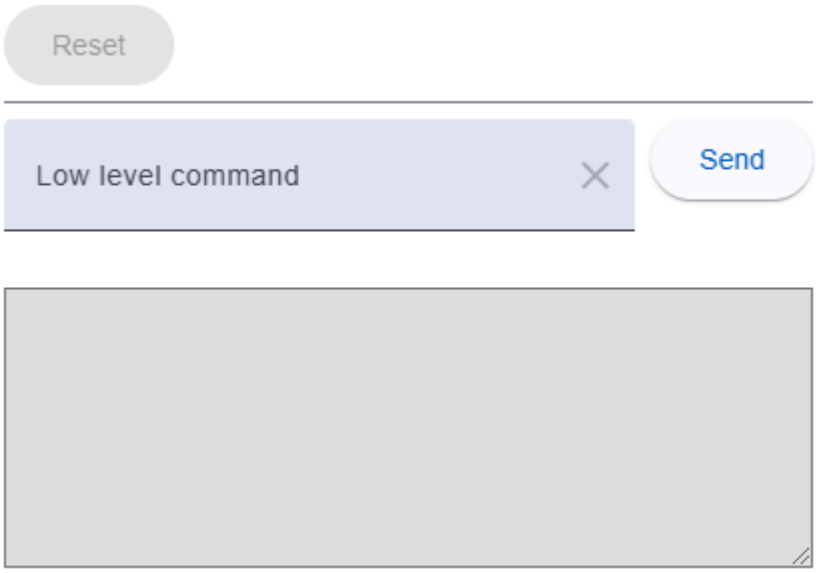
Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Name**: Message id or variables defined by this device driver.
- **Value**: Value of message id or variables defined by this device driver.

2.3.2.1.3 Maintenance page



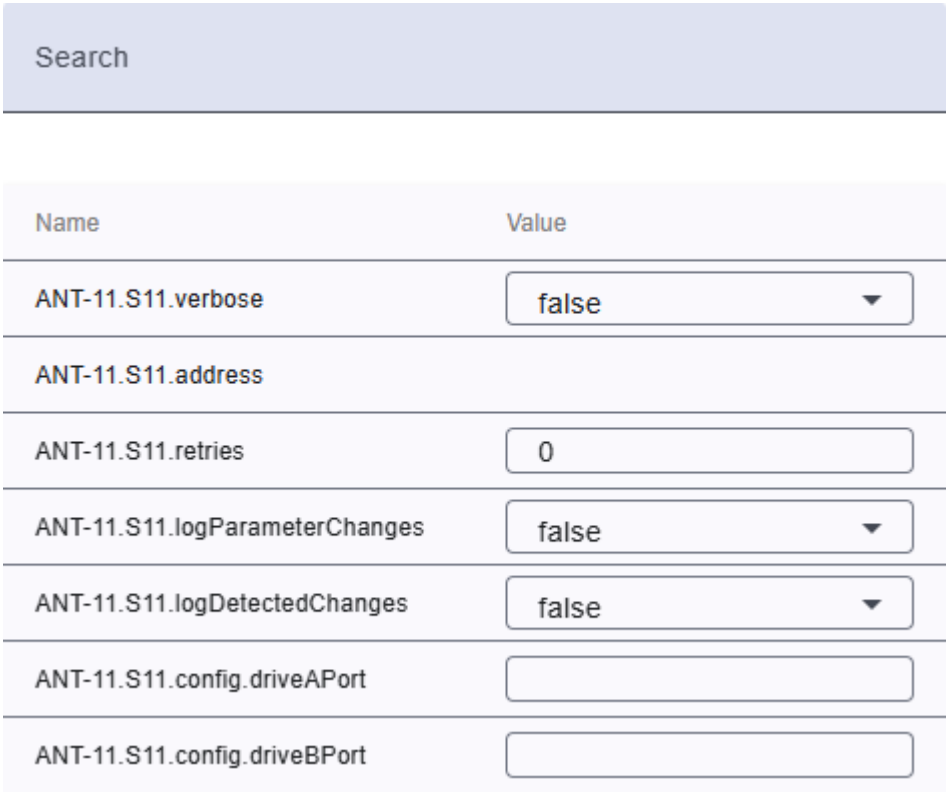
Reset: Resets the device.

Low level command: Command to check check the value.

Send: Send the low level command.

Text area: Shows the returned value of command.

2.3.2.1.4 Config page



Search bar: Allows users to filter events by keywords.

Header row

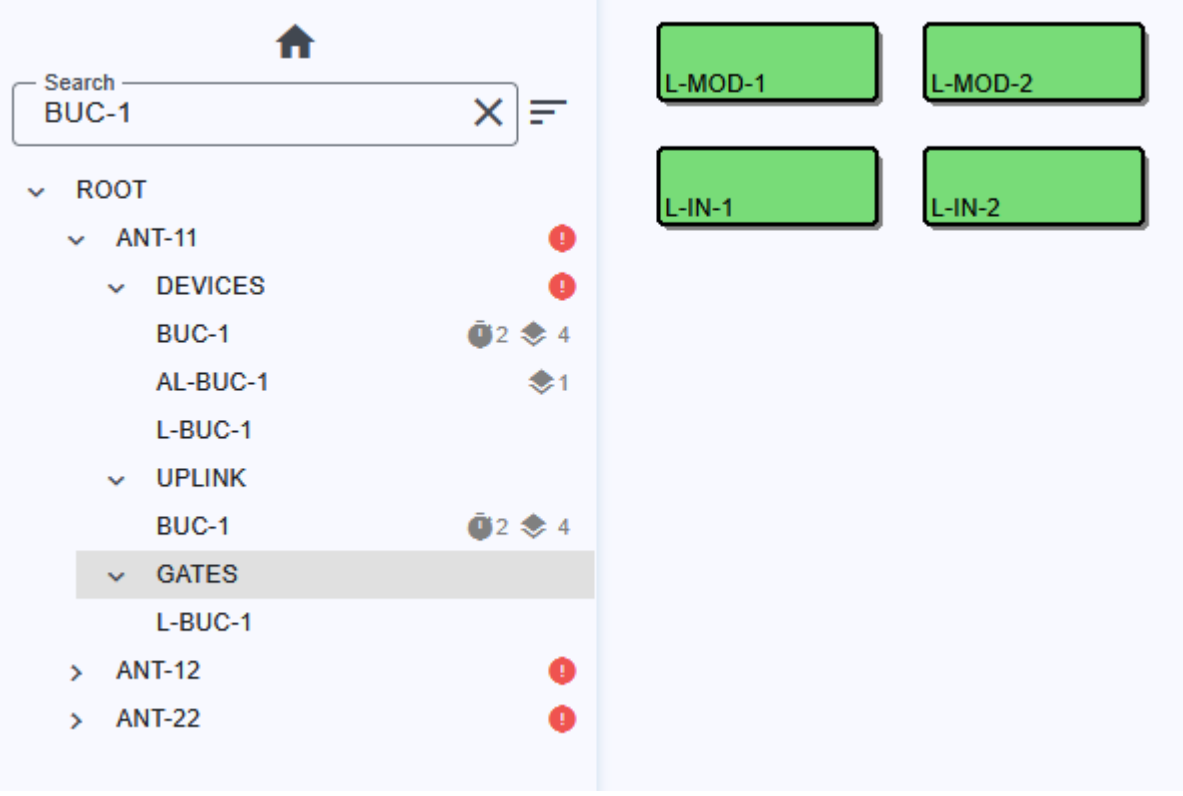
- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Name**: Configurable parameters.
- **Value**: Value of the parameters. The values can be changed by clicking on input fields. After you have changed the value in the input fields, simply press the `enter` key or click with the mouse outside the input field to send the values. Press the `esc` key to discard or undo changes. It works only with input fields not with dropdowns

2.4 Treeview

The so call Treeview provides a list of devices of all connected MNC system organized in a tree. It can be accessed from the sidebar *tree icon* below the logo. You can arrange the devices and sub-trees in the Treeview Editor



- **Home icon**: Hide the treeview.
- **Search**: filter devices by name
- **Sort**: Tree can be sorted by

    - ascending device name
    - descending device name
    - default: as definded in TreeView Editor (natural order)

The tree shows all connected MNC's as top node and the configured subsystems. Each node can have one or more devices attached.

Each device node is marked with its fault state with icons

- no icon: ok
- grey icon: state cannot be determined
- yellow icon: device summary state is warning
- red icon: device summary state is fault or alarm

Subsystem nodes inherit the fault state from the subordinate elements, summed up from the devices and subsystems.

Devices with **masked** or **delayed** faults will additionally show the count of these faults.

Functionality

- **>** : Expand the node.
- **<** : Collapse the node.
- **Click on node**: expands the node and will be load configured screen. If no screen for this subsystem is defined it shows device icons of all devices which belongs to the subsystem.
- **Click on device**: Opens device details panel on right hand side

2.5 Channel database

The Channel Database is a central store for receive and transmit channels. These settings are used to configure equipment for receiving or transmitting to a satellite or on an IP network (streaming).

The title bar provides access to the three different channel types:

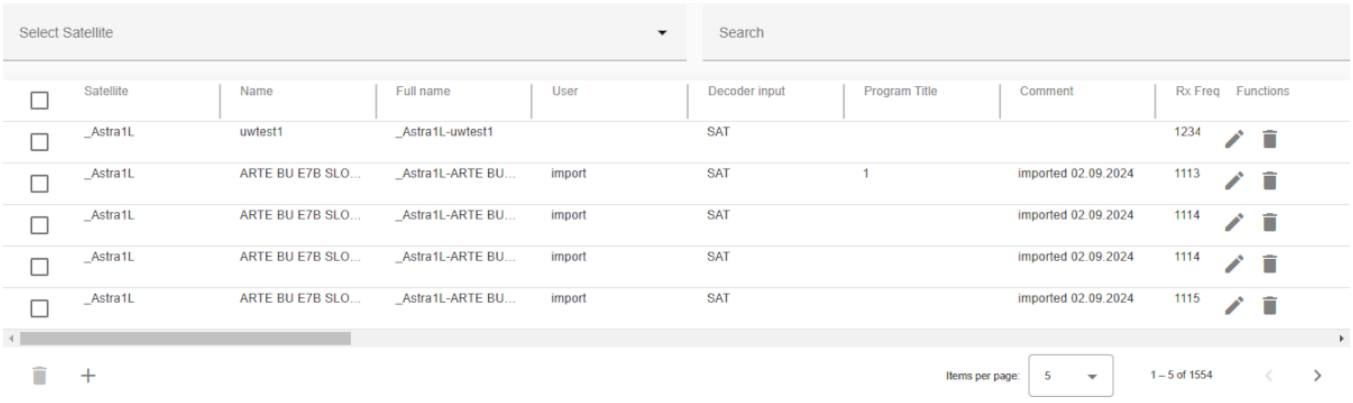
- Satellite channels (default)
    - satellite channels include parameters like frequency, modulation type
    - transmit and receiving via satellite is supported
    - basic audio/video settings are also part of these channels
- IP/Streaming channels
    - IP channels support various network streaming protocols like UDP or RTP
    - transmit and receiving via network is supported
    - basic audio/video settings are also part of these channels
- ASI channels
    - basically ASI channels are only to address the ASI inputs of IRDs
    - there are no specific settings on the ASI interface needed
    - basic audio/video settings are also part of these channels

You can choose which type of channels you want by clicking on the buttons at the top of this page.

On a system without installed SatDB or if the PostgreSQL Database is not reachable an error message will be display: Error DB not reachable. In this case, please check your database installation.

2.5.1 Satellite channels

The list of all satellite channels in the database. The table can be scrolled horizontally. Satellite and functions row are sticky.



Satellite channels define the common paramaters of receive equipment (e.g. IRDs, Demodulator) and transmit equipment (e.g. Modulators) for satellite transmission. Typically used for the contribution of newsfeeds or TV over satellite but not limited to. Each channel belongs to a satellite which needs to be configured in the Satellite Database.

To use this database you have to configure the corresponding Channel-Devices on the MNC server(s) which controlls the equipment.

For receive applications the following logical devices are available:

- RX-Channel-ByChannel
- RX-Channel-BySatellite
- RX-Channel-ActivationBased

For transmit applications the following logical devices are available:

- TX-Channel-ByChannel
- TX-Channel-BySatellite

These logical devices will retrieve the channel information directly from the central database. Please refer to the linked documentation for details how to setup and use the RX and TX Channel devices.

Search bars

- Located at the top of the table.

- Allows users to filter by:
  - *Satellite*: select one satellite from the list to display all related channels
  - *Keywords*: full-text search over all channels and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.
- You can arrange the width of an row by `click + hold + drag` near from the header name (grey border)

Table columns

The first column located at the far left of the table provides a checkbox to select one or more channels (rows) and perform the same operation on all selected channels.

- **Single Selection**: Click on a single checkbox to select an individual channel
- **Multiple Selection**: Click multiple checkboxes to select multiple channels.
- **Select all**: The checkbox in the header row allows you to select or deselect all channels on all pages.

The following function(s) are available:

Function	Icon	Description
delete		delete the selected channels from the database

The last column located at the far right of the tables provides buttons to run actions on the corresponding channel.

The following functions for managing a channel are `available` :

Function	Icon	Description
Delete		to delete the channel
Edit		modify/edit channel

The following buttons for global function(s) are available at the the bottom of the table:

Function	Icon	Description
Add		add a new channel

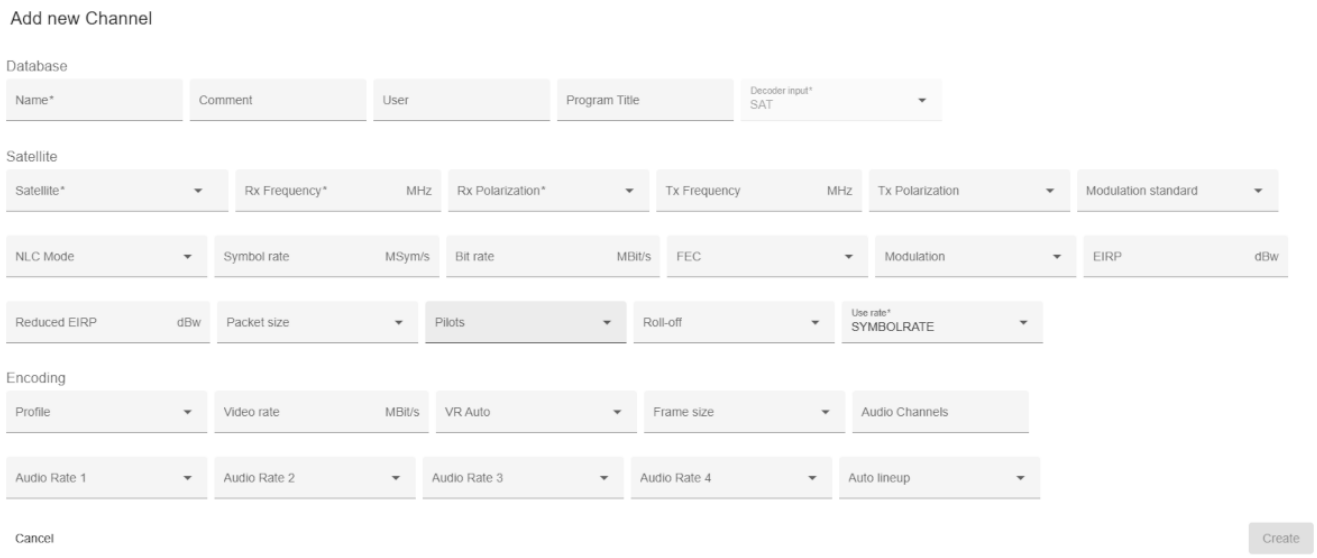
Function	Icon	Description
Delete		to delete all selected the channels
Page	Pagination controls	set the number of items displayed per page (e.g., 5, 10, or 25) and navigate between pages

The satellite channel table contains the following columns:

Column name	Description
Satellite	name of satellite
Name	user defined channel name
Full name	automatically generated full name (`satellite's name` + `-` + `Name`)
User	free text to enter a user name which is responsible for this database entry
Program title	name of the program transmitted or received with this channel
Comment	one line comment describing this satellite channel
Rx frequency	receive frequency in MHz.
Rx pol.	receive polarization
Tx frequency	transmit frequency in MHz
Tx pol.	transmit polarization
Mode	modulation standard
NLC mode	NLC (Non Linear Constellation) mode for NS4 modulation
Symbol rate	symbol rate in MSym/sec
FEC	FEC rate
Modulation	modulation type
Roll-off	roll off factor
Pilots	pilots on/off switch
Bit rate	data rate in MBit/sec
Use rate	selects the way the data rate is specified

Column name	Description
Packet size	packet size
Frame size	frame size
Video rate	video data rate in MBit/sec
VR auto	video rate auto switch
Profile	video encoding profile
EIRP	transmit EIRP in dBW
Reduced EIRP	reduced EIRP for line up in dBW
Auto lineup	configures automatic line up
Audio rate 1	audio channel 1 data rate
Audio rate 2	audio channel 2 data rate
Audio rate 3	audio channel 3 data rate
Audio rate 4	audio channel 4 data rate
Audio channels	Number of audio channels.

2.5.1.1 Add/Edit satellite channel dialog



The Add or Edit satellite channel dialog shows up on

- click on button on the bottom toolbar
- click on in the channel row

The dialog title clearly indicates whether you are creating a new channel or editing an existing one, ensuring clarity in the action being performed.

Required fields are marked with an asterisk `*`. Fields which you don't plan to use in your installation (e.g. TX settings if you only receive channels) can be can remain empty or on defaults. Certain setting will anyway only be applied to equipment if this is configured in the RX/TX-Channel devices.

Field	Description
Name*	user defined channel name, must be unique
Comment	describe this satellite channel
User	free text to enter a user name which is responsible for this database entry, must not match to a username of this M&C system
Program title	name of the program transmitted or received with this channel
Decoder input	*read-only* channel type
Satellite*	select a satellite name to which this channel belongs to
Rx frequency*	receive frequency in MHz (3 digits precision)
Rx polarization*	receive polarization, one of `X` (Horizontal), `Y` (Vertical), `L` (LHCP) or `R` (RHCP)
Tx frequency	transmit frequency in MHz (3 digits precision).
Tx polarization	transmit polarization, one of `X` (Horizontal), `Y` (Vertical), `L` (LHCP) or `R` (RHCP)
Modulation standard	DVB mode should be one of the option from the drop-down list.
NLC mode	enable (`ON`) or disable (`OFF`) NLC mode for NS4 modulations
Symbol rate	symbol rate in MSym/sec (4 digits precision)
Bit rate	data rate in MBit/sec (4 digits precision)
FEC	select FEC rate from drop-down list

Field	Description
Modulation	select modulation from drop-down list
EIRP	transmit EIRP in dBW (2 digits precision)
Reduced EIRP	reduced EIRP for line-up in dBW (2 digits precision)
Packet size	packet size, one of `188` or `204`
Pilots	enable (`ON`) or disable (`OFF`) pilots
Roll-off	select roll off factor from drop-down list
Use rate	selects the way the data rate is specified: by `SYMBOLRATE` (default) or by `BITRATE` . Make sure that the corresponding rate is also stored with this channel.
Profile	select video encoding profile from drop-down list
Video rate	video data rate in MBit/sec (4 digits precision)
VR auto	video rate auto switch, one of `FIXED` or `AUTO`
Frame size	frame size, one of `SHORT` or `NORMAL`
Audio channels	number of audio channels between 1-4
Audio rate 1	audio channel 1 data rate select from drop-down list
Audio rate 2	audio channel 2 data rate select from drop-down list
Audio rate 3	audio channel 3 data rate select from drop-down list
Audio rate 4	audio channel 4 data rate select from drop-down list
Auto lineup	enable (`ON`) or disable (`OFF`) automatic line up

The following actions are `available` :

Function	Description
Create	For new channel, this creates the channel with the provided details
Save	For existing channel, this saves modifications.
Cancel	Closes the dialog without saving

The form tests the input fields for validity and display hints in red in each field with wrong

input. If an error occurs in the input fields, the button Create/Save button is deactivated.

2.5.1.2 On delete confirmation dialog

The Delete confirmation dialog shows up on

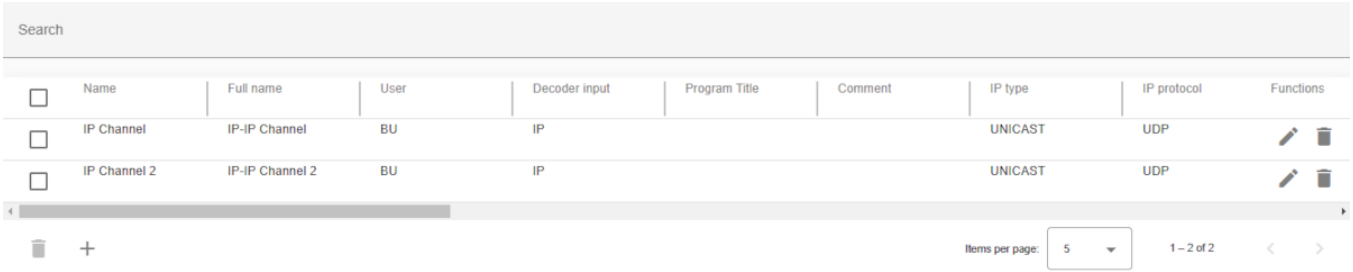
- click on in the table row on the bottom toolbar

The following actions are `available` :

Function	Description
Yes	Deletes the channel(s) permanently
Cancel	Cancels the deletion action

2.5.2 IP channels

The list of all IP / Streaming channels in the database. The table can be scrolled horizontally. Name and functions row are sticky.



IP channels define the common parameters for receiving and transmitting IP streams. Typically used in news contribution over Internet but not limited to. Each channel contains source and/or destination addresses and information of the used streaming protocol.

To use this database you have to configure the corresponding Channel-Devices on the MNC server(s) which controlls the equipment.

For receive applications the following logical devices are available:

- RX-Channel-ByChannel
- RX-Channel-BySatellite
- RX-Channel-ActivationBased

For transmit applications the following logical devices are available:

- TX-Channel-ByChannel
- TX-Channel-BySatellite

These logical devices will retrieve the channel information directly from the central database.

Please refer to the linked documentation for details how to setup and use the RX and TX Channel devices.

Search bars

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all channels and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.
- You can arrange the width of an row by `click + hold + drag` near from the header name (grey border)

Table columns

The first column located at the far left of the table provides a checkbox to select one or more channels (rows) and perform the same operation on all selected channels.

- **Single Selection**: Click on a single checkbox to select an individual channel
- **Multiple Selection**: Click multiple checkboxes to select multiple channels.
- **Select all**: The checkbox in the header row allows you to select or deselect all channels on all pages.

The following function(s) are available:

Function	Icon	Description
delete		delete the selected channels from the database

The last column located at the far right of the tables provides buttons to run actions on the corresponding channel.

The following functions for managing a channel are `available` :

Function	Icon	Description
Delete		to delete the channel
Edit		modify/edit channel

The following buttons for global function(s) are available at the the bottom of the table:

Function	Icon	Description

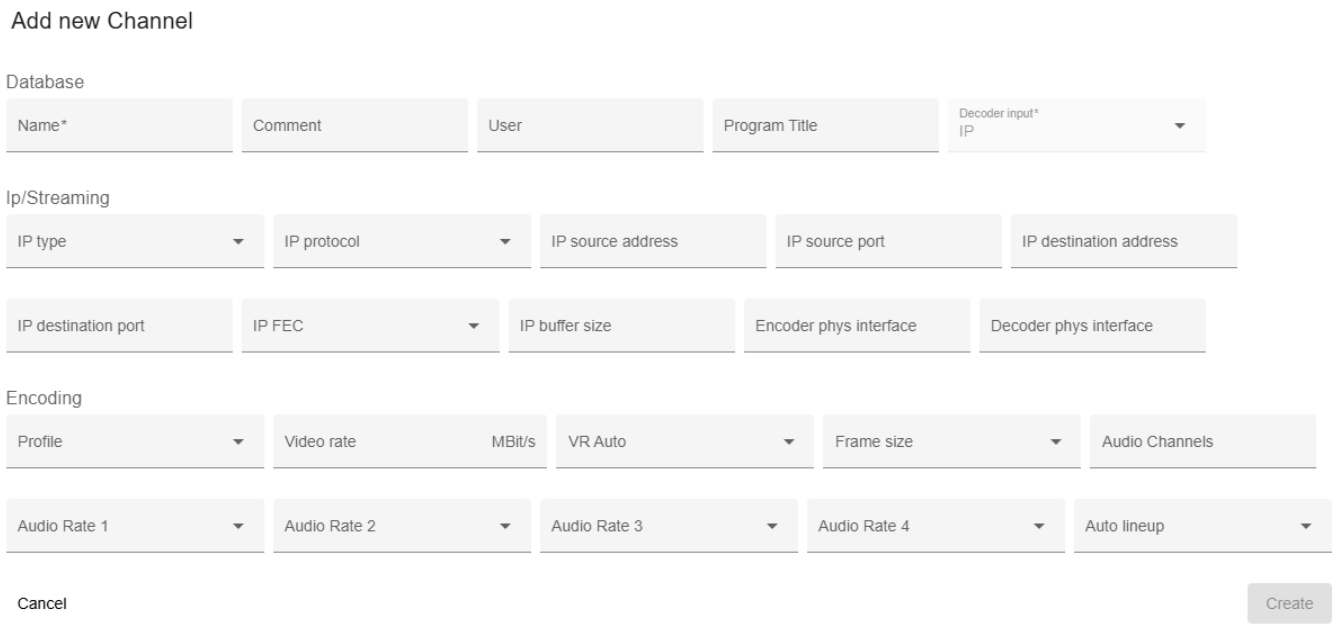
Function	Icon	Description
Add	+	add a new channel
Delete	🗑	to delete all selected the channels
Page	Pagination controls	set the number of items displayed per page (e.g., 5, 10, or 25) and navigate between pages

The IP channel table contains the following columns:

Column name	Description
Name	user defined channel name
Full name	automatically generated full name (IP + - + Name)
User	free text to enter a user name which is responsible for this database entry
Program title	name of the program transmitted or received with this channel
Comment	one line comment describing this satellite channel
IP type	IP addressing type
IP protocol	IP streaming protocol
IP source address	Source IP address
IP source port	Source port number
IP destination address	Destination IP address
IP destination port	Destination port number
IP FEC	IP FEC selection
IP buffer size	Buffer size
Encoder phys.int	Encoder physical output number
Decoder phys.int.	Decoder physical input number
Frame size	The frame size
Video rate	video data rate in MBit/sec
VR auto	video rate auto switch
Profile	video encoding profile

Column name	Description
Auto lineup	configures automatic line up
Audio rate 1	audio channel 1 data rate
Audio rate 2	audio channel 2 data rate
Audio rate 3	audio channel 3 data rate
Audio rate 4	audio channel 4 data rate
Audio channels	Number of audio channels.

2.5.2.1 Add/Edit IP channel dialog**



The Add or Edit IP channel dialog shows up on

- click on + button on the bottom toolbar
- click on ✎ in the channel row

The dialog title clearly indicates whether you are creating a new channel or editing an existing one, ensuring clarity in the action being performed.

Required fields are marked with an asterisk `*` . Fields which you don't plan to use in your installation (e.g. TX settings if you only receive channels) can be can remain empty or on defaults. Certain setting will anyway only be applied to equipment if this is configured in the RX/TX-Channel devices.

Field	Description

Field	Description
Name*	user defined channel name, must be unique
Comment	describe this IP channel
User	free text to enter a user name which is responsible for this database entry, must not match to a username of this M&C system
Program title	name of the program transmitted or received with this channel.
Decoder input	*read-only* channel type
IP type	IP addressing type, one of `UNICAST` or `MULTICAST`
IP protocol	IP protocol, one of `UDP`, `RTP`, `TCP` or `ZIXI`
IP source address	source IP address in dotted quad notation
IP source port	source port number `0-65535`
IP destination address	destination IP address in dotted quad notation
IP destination port	destination port number `0-65535`
IP FEC	IP FEC selection, one of `OFF` or `ON`
IP buffer size port	buffer size
Encoder phys.int.	encoder physical output number (1-4)
Decoder phys.int.	decoder physical input number (1-4)
Profile	select video encoding profile from drop-down list
Video rate	video data rate in MBit/sec (4 digits precision)
VR auto	video rate auto switch, one of `FIXED` or `AUTO`
Frame size	frame size, one of `SHORT` or `NORMAL`

Field	Description
Audio channels	number of audio channels should be between 1-4
Audio rate 1	audio channel 1 data rate select from drop-down list
Audio rate 2	audio channel 2 data rate select from drop-down list
Audio rate 3	audio channel 3 data rate select from drop-down list
Audio rate 4	audio channel 4 data rate select from drop-down list

The following actions are `available` :

Function	Description
Create	For new channel, this creates the channel with the provided details
Save	For existing channel, this saves modifications.
Cancel	Closes the dialog without saving

The form tests the input fields for validity and display hints in red in each field with wrong input. If an error occurs in the input fields, the button Create/Save button is deactivated.

2.5.2.2 On delete confirmation dialog

The Delete confirmation dialog shows up on

- click on in the table row on the bottom toolbar

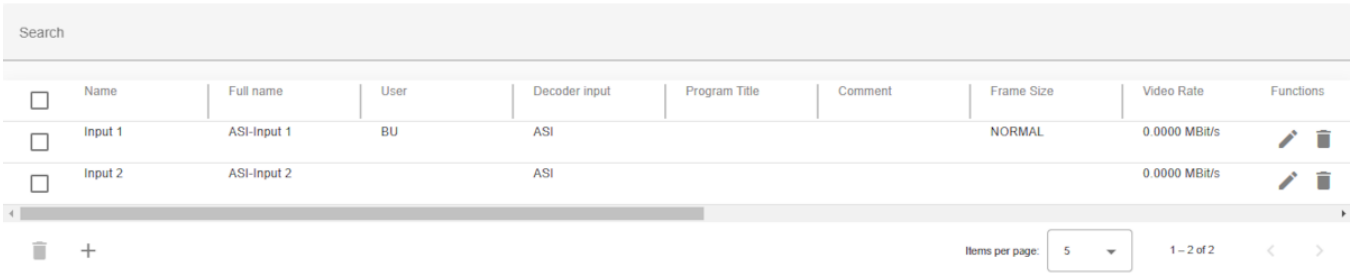
The following actions are `available` :

Function	Description
Yes	Deletes the channel(s) permanently
Cancel	Cancels the deletion action

2.5.3 ASI channels

The list of all ASI channel records in the database. The table can be scrolled horizontally. Name

and functions row are sticky.



Some receives (e.g. IRDs) provides between Satellite- and IP-Inputs also plain ASI inputs. In this mode no configuration of the input is required, you just have to switch to ASI input. Therefore the related channels are used in most cases as placeholder and to setup encoding (audio,video settings) in case that the receiver get a signal to ASI input. Nevertheless these channel type is available to allow a consistent operation with all input methods.

For receive applications the following logical devices are available:

- RX-Channel-ByChannel
- RX-Channel-BySatellite
- RX-Channel-ActivationBased

For transmit applications the following logical devices are available:

- TX-Channel-ByChannel
- TX-Channel-BySatellite

These logical devices will retrieve the channel information directly from the central database. Please refer to the linked documentation for details how to setup and use the RX and TX Channel devices.

Search bars

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all channels and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.
- You can arrange the width of an row by `click + hold + drag` near from the header name (grey border)

Table columns

The first column located at the far left of the table provides a checkbox to select one or more channels (rows) and perform the same operation on all selected channels.

- **Single Selection**: Click on a single checkbox to select an individual channel
- **Multiple Selection**: Click multiple checkboxes to select multiple channels.
- **Select all**: The checkbox in the header row allows you to select or deselect all channels on all pages.

Function	Icon	Description
delete		delete the selected channels from the database

The last column located at the far right of the tables provides buttons to run actions on the corresponding channel.

The following functions for managing a channel are `available` :

Function	Icon	Description
Delete		to delete the channel
Edit		modify/edit channel

The following buttons for global function(s) are available at the the bottom of the table:

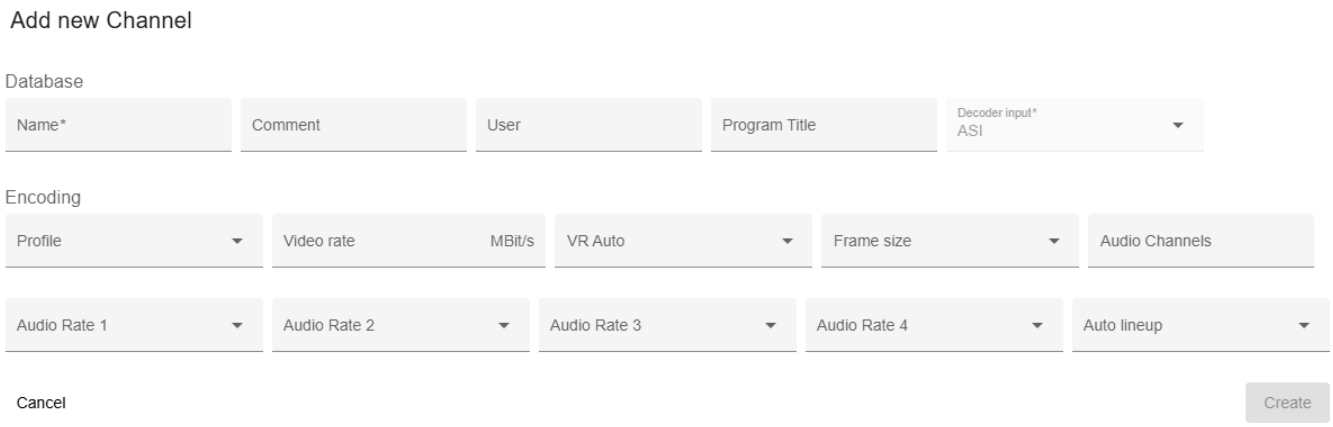
Function	Icon	Description
Add		add a new channel
Delete		to delete all selected the channels
Page	Pagination controls	set the number of items displayed per page (e.g., 5, 10, or 25) and navigate between pages

The ASI channel table contains the following columns:

Column name	Description
Name	user defined channel name
Fullname	automatically generated full name (`IP` + `-` + `Name`)
User	name of the user who lastly edited the channel
Program title	name of the program transmitted or received with this channel
Comment	one line comment describing this satellite channel
Frame size	frame size

Column name	Description
Video rate	video data rate in MBit/sec
VR auto	video rate auto switch
Profile	video encoding profile
Audio channels	number of audio channels between 1-4
Audio rate 1	audio channel 1 data rate select from drop-down list
Audio rate 2	audio channel 2 data rate select from drop-down list
Audio rate 3	audio channel 3 data rate select from drop-down list
Audio rate 4	audio channel 4 data rate select from drop-down list

2.5.3.1 Add/edit ASI channel dialog**



The Add or Edit ASI channel dialog shows up on

- click on + button on the bottom toolbar
- click on ✎ in the channel row

The dialog title clearly indicates whether you are creating a new channel or editing an existing one, ensuring clarity in the action being performed.

Required fields are marked with an asterisk `*`. Fields which you don't plan to use in your installation (e.g. TX settings if you only receive channels) can be can remain empty or on defaults. Certain setting will anyway only be applied to equipment if this is configured in the RX/TX-Channel devices.

Field	Description
Name*	user defined channel name, must be unique

Field	Description
Comment	describe this IP channel
User	free text to enter a user name which is responsible for this database entry, must not match to a username of this M&C system
Program title	name of the program transmitted or received with this channel.
Decoder input	*read-only* channel type
Profile	select video encoding profile from drop-down list
Video rate	video data rate in MBit/sec (4 digits precision)
VR auto	video rate auto switch, one of `FIXED` or `AUTO`
Frame size	frame size, one of `SHORT` or `NORMAL`
Audio channels	number of audio channels should be between 1-4
Audio rate 1	audio channel 1 data rate select from drop-down list
Audio rate 2	audio channel 2 data rate select from drop-down list
Audio rate 3	audio channel 3 data rate select from drop-down list
Audio rate 4	audio channel 4 data rate select from drop-down list

The following actions are `available` :

Function	Description
Create	For new channel, this creates the channel with the provided details
Save	For existing channel, this saves modifications.
Cancel	Closes the dialog without saving

The form tests the input fields for validity and display hints in red in each field with wrong

input. If an error occurs in the input fields, the button Create/Save button is deactivated.

2.5.3.2 On delete confirmation dialog

The Delete confirmation dialog shows up on

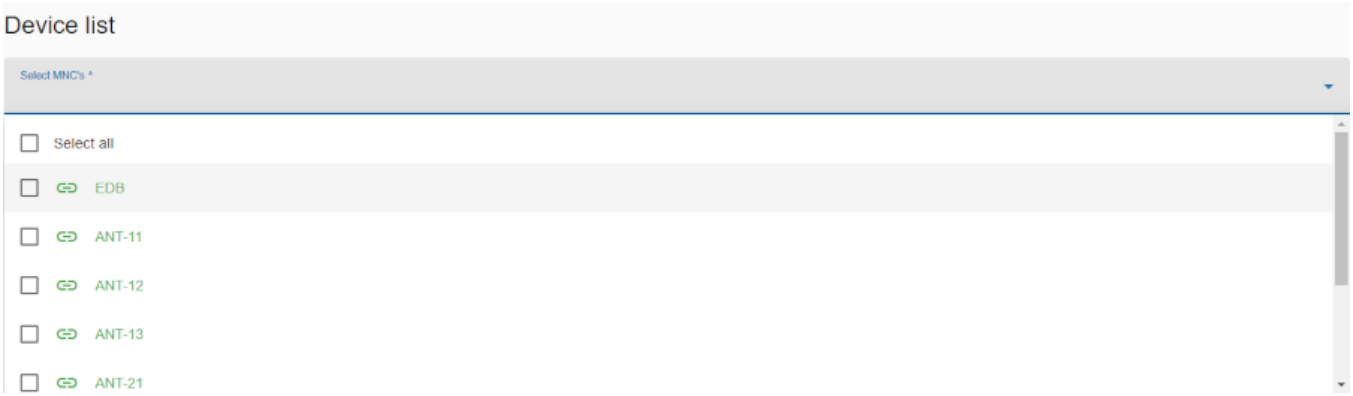
- click on in the table row on the bottom toolbar

The following actions are `available` :

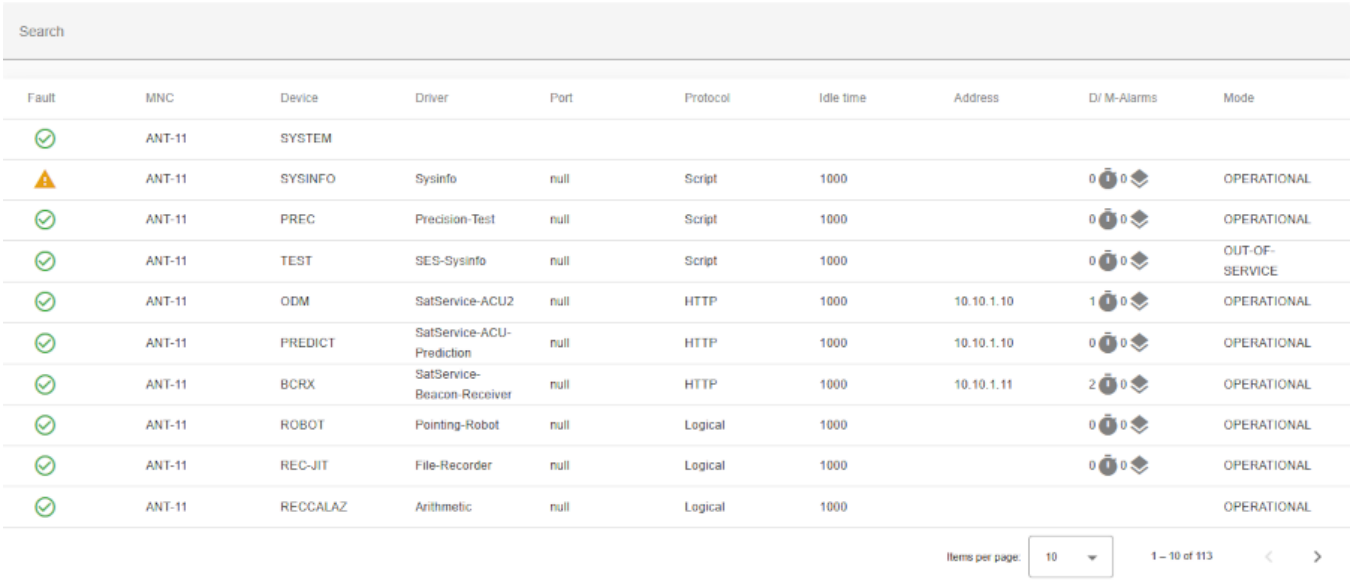
Function	Description
Yes	Deletes the channel(s) permanently
Cancel	Cancels the deletion action

2.6 Device list

The device list page shows different type of information about installed devices. For example driver name, protocol, mode or fault state. You can choose one or multiple MNCs to search and list devices.



In the first step select one or more MNCs from the drop down list below the heading. The page will show a table of alle devices.



Search bar

- Located at the top of the table.
- Allows users to filter device list
- The search pattern will be used for a full text search in all columns of the table.

Header row

- You can sort rows in ascending or descending order by clicking on the column header (e.g. MNC, device, etc.).
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is indicated by an arrow or icon near the column name.

Table columns

- **Fault**: Current fault of device on MNC. If there is no fault, a green*check icon* appears, if there is a warning, an orange *warning icon* appears and if there is a summary fault, a red *error icon* appears.
  - **Functionality**: On mouse hover on fault icons gives you detailed information.
- **MNC**: MNC name.
- **Device**: Device name.
- **Driver**: Device driver.
- **Port**: The communication port/interface.
- **Protocol**: The used protocol type.
- **Idle time**: The idle time in milliseconds.
- **Address**: Address.
- **D/M-alarms**: Delayed alarms are labelled with a clock icon and masked alarm with layers icon
- **Mode**: Current mode of device.
  - **Functionality**: On click on mode row, open device details panel.

Bottom toolbar

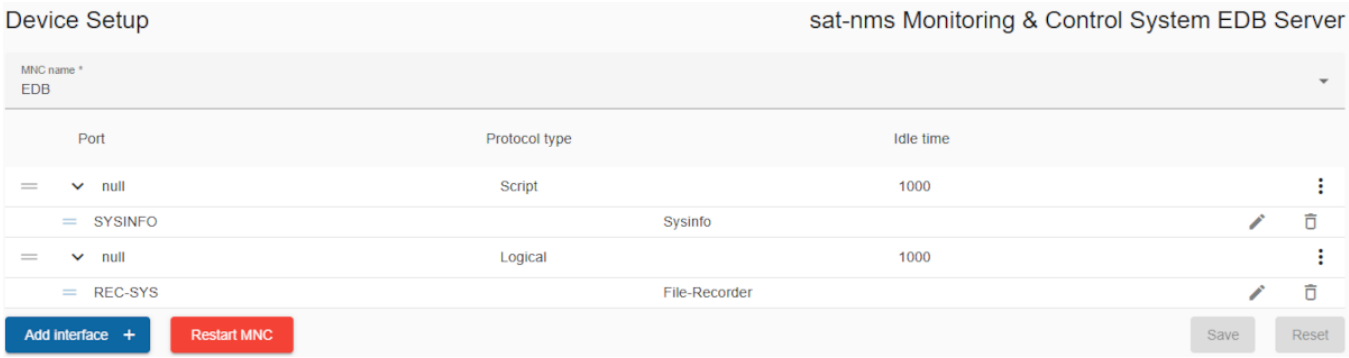
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

Functionality

- **Open device window**: On click on row expect on mode column opensdevice window.
- **Open device panel**: On click on mode row, opendevice details panel.

2.7 Device setup

With the ***sat-nms*** M&C software, the assignment which type of device is controlled by which communication interface and which driver is free configurable. The user interface of the software provides a configuration window which enables the authorized operator to setup devices.



When an operator is going to configure an MNC first it is important to understand, that with the ***sat-nms*** software each interface is bound to a communication protocol. The communication protocol used for a certain device is not unchangeably linked to the device driver. This is to support multiple devices being controlled via a single interface. Devices using a common 'multi drop' capable protocol may be connected to the MNC with a serial but like RS485.

Once an interface (serial port or network) has been included into the setup and got a communication protocol assigned to it, within the setup devices can be attached to this interface. With the device definition, the device gets a name and a device driver assigned to it. The device's name acts as an address within the software where to send at commands (equipment settings) to, the device driver tells the software how to treat the device at a low communication level.

To configure device first select the MNC:

MNC name: Select an MNC to load devices and start editing.

This will show a list of all already configured interface and their attached devices.

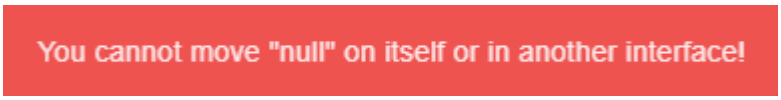
The first level of this tree represents the interface.

- **Port**: Displays the name of the port or node.

- **Protocol** Type: Indicates the protocol associated with the entry.
- **Idle Time**: Shows the idle time for the specific entry (in milliseconds).

One or more devices can be attached to one interface.

- **Parent node/Interface** These are the primary entries that may have child nodes/devices nested under them. Parent nodes or interfaces are identified by a dropdown arrow (▼) on the left side of the row, allowing you to expand or collapse their child nodes.
- **Drag Handles**: Located on the left of each row (indicated by the three horizontal lines). Users can drag and drop rows to rearrange the list dynamically. But parent nodes/interfaces cannot be moved into another interface. At the bottom of the page, the snack bar (error) would be displayed with the description of the error, as shown below.



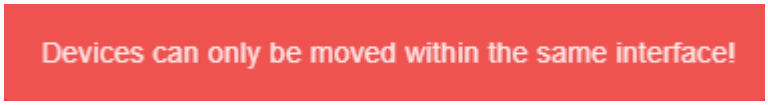
Expandable/Collapsible Rows = Interfaces

Rows with sub-items have a toggle arrow on the left side. Clicking the arrow expands or collapses the child node or devices.

- **Context Menu**: Accessible via the three-dot icon on the right of each row, provides the following options:
  - **Add Interface Below**: Inserts a new interface directly below the selected interface.
  - **Add Device**: Adds a new device as a child node under the selected interface.
  - **Edit Interface**: Opens a dialog to modify the details of the selected interface.
  - **Delete Interface**: Removes the selected interface and all its devices from the list.

Child Nodes = Devices These are nested entries directly associated with a parent node or interface. Child nodes or devices are indented beneath their respective parent node or interface to visually indicate the hierarchy.

- **Drag Handles**: Located on the left of each row (indicated by the three horizontal lines). Users can drag and drop rows to rearrange the list dynamically. However, devices cannot be moved from one interface to another interface. At the bottom of the page, the snack bar (error) would be displayed with the description of the error, as shown below.

- **Device name**: Name of the near the drag handel
- **Device driver**: Next to device name is device driver.
- **Edit device**: If you click on the *pencil icon* on the right-hand side, you can edit the device details.
- **Delete device**: Click the *trash icon* on the right hand side to delete an device from list.

Functions

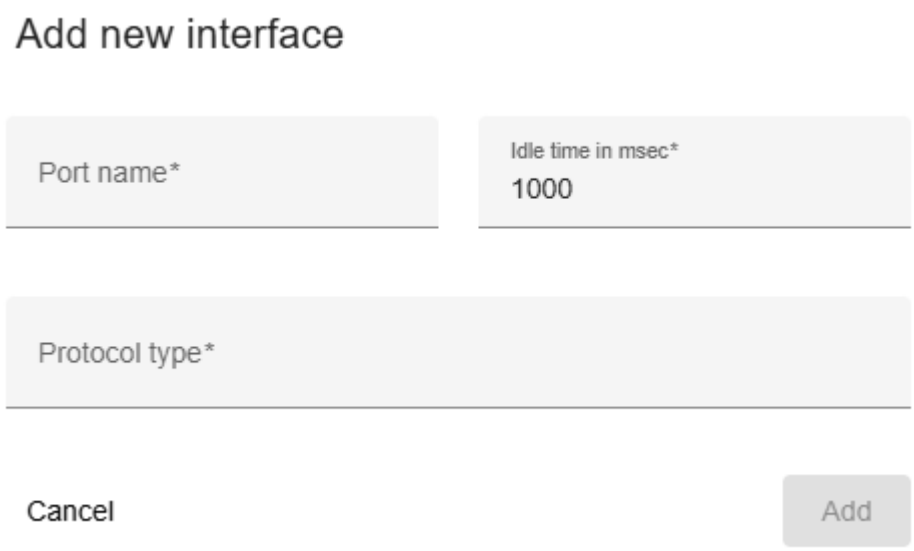
- **Add interface**: Found at the bottom left of the editor. Clicking this opens a dialog to add

a new interface to the list.

- **Restart MNC**: Clicking this button will restarts the selected MNC. Of course only after your confirmation via dialog. You must do this, to make the target system use a modified equipment setup.
- **Save**: Saves all changes made in the editor. If you have not saved the changes and accidentally leave the editor, a confirmation dialog will appear in which you must give your consent to leave the editor/page.
- **Reset**: Discards all unsaved changes and reverts to the first loading state.

2.7.1 Dialogs

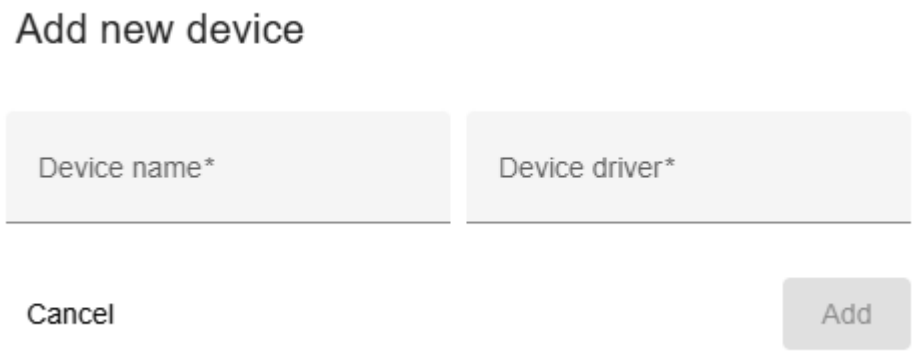
Add/edit interface



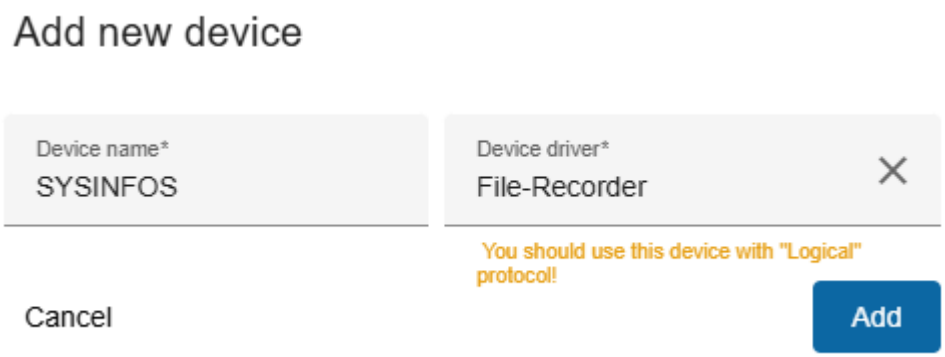
- **Trigger**:
  - when you click on the "Add interface +" button on the bottom to create new interface or
  - an on *pencil icon* to edit from context menu or
  - on *down arrow Add interface below*to add interface from context menu
  - The dialog title clearly indicates whether you are creating a new interface, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Port name**: The communication port / interface that thread should use.
    - **null**: The null interface is used by all logical devices. In every M&C system there is exactly one null interface running the Logical protocol. All logical devices are connected to this (physically not existent) interface.
  - **Idle time in msec**: The idle time of thread (msec).
  - **Protocol type**: The protocol for thread. It should be one of drop-down options.
- **Actions**:
  - **Add/Save**:
    - For new interface, this creates the interface with the provided details.

        - For existing interface, this saves modifications.
        - If an error occurs in the input fields, the button is deactivated.
    - **Cancel**: Closes the dialog without saving.

Add/edit device



- **Trigger**:
    - when you click on *Add device +* to add device from context menu or
    - an on *pencil icon* to edit from device from row or
    - The dialog title clearly indicates whether you are creating a new interface, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
    - **Device name**: The name of the device. It must be unique.
    - **Device driver**: The device driver. It should be one of the option from the drop-down list. If you select the wrong device driver for the interface protocol, a warning is displayed and it is displays which protocol you should use for this device like in image below.



- **Actions**:
    - **Add/Save**:

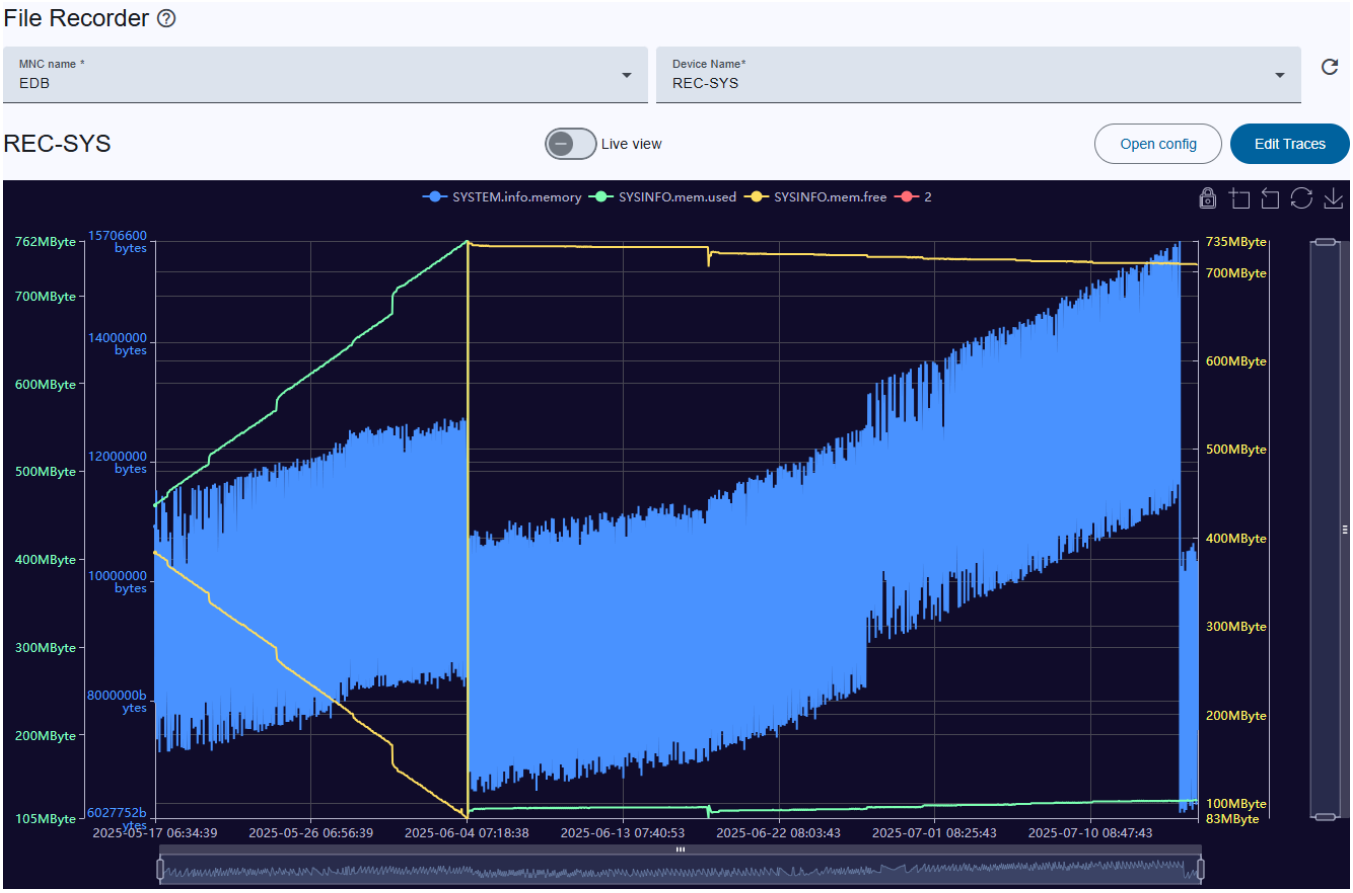
        - For new device, this creates the device with the provided details.
        - For existing device, this saves modifications.
        - If an error occurs in the input fields, the button is deactivated.
    - **Cancel**: Closes the dialog without saving.

Confirmation dialog

- **Trigger**: Opens when you click the
    - Trash icon for an device from menu column
    - Trash icon from bottom toolbar.
    - Reset button
    - Leaving the page if there are unsaved changes.
- **Content**: Asks the user to confirm the action, depending on where you trigger the dialog.
- **Actions**:
    - **Yes**: Confirm the action.
    - **Cancel**: Cancels the action.

2.8 File recorder

The sat-nms M&C software provides a facility (a logical device) called File-Recorder which is capable to record arbitrary data like levels, antenna pointing etc. into a disc file. The File recorder page is the user interface to inspect such files. The page can be accessed either from the side toolbar File-Recorder menu or can be configured in user-screens on button-element as File-Recorder action.



Top toolbar

- **MNC name**: A dropdown to select the available MNC from drop-down.
- **Device name**: A dropdown to select the available file-recorder devices from drop-down.
- **Reload**: A button to reload the file-record data.

Title, live view, and configuration buttons

- **Title**: Displays the currently selected device name (e.g., "REC-SYS").
- **Live view toggle**: Beside for viewing stored log files, the File recorder Viewer can be used to display the logged data as it is acquired with an automated display update. By pressing the "live view" toggle button, the viewer changes to live view mode. In this mode the viewer shows up to 400 recent data points, automatically updated with an interval that is configurable separately from the standard interval at the device window setup (open config button).
- **Configuration buttons**:
  - **Open config**: Opens a device window allowing users to view or modify settings.
  - **Edit traces**: Opens a dialog for customizing or editing trace parameters, such as specific trace name and their units.

Graph

- **Legends**:
  - Positioned at the top of the graph, legends display the names of the traces.
  - **Interactive Features**: Clicking on a legend hides or shows the corresponding trace line on the graph for better visualization.
- **Zoom actions**: *Described below under zoom control buttons (near the legend)*
- **Graph lines and axes**:
  - **Graph lines**: Display the traces values over time, represented in different colors as per the legend.
  - **Y-axis**:
    - **Left**: Displays the primary value ranges for the traces.
    - **Right**: Displays secondary value ranges for specific traces.
  - **X-axis (bottom)**: Represents the timeline of the data being monitored.
- **Zooming**
  - **Lock Y-Axis**: By clicking on the lock symbol, the y-axis is locked and the user can interact with the diagram without scaling.
  - **Scrolling in and out**: Use the scroll wheel to zoom in or out horizontally along the timeline (X-axis).
  - **Vertical zoom (y-axis right side)**: Adjusts the zoom level vertically, allowing focus on specific Y-axis value ranges.
  - **Horizontal zoom (x-axis bottom)**: Slider enables horizontal zooming along the timeline, allowing you to focus on specific time intervals.
  - **Zoom control buttons (near the legend)**:
    - **Zoom brush (left)**: Enables manual zooming by selecting an area on the graph.
    - **Undo zoom**: Resets the graph to the previous zoom level.
    - **Restore**: Resets the graph to its default view (original scale).
    - **Save as image**: Exports the current graph as an image file.

2.8.1 Functionality

Graph interaction

- **Zooming**
  - **Sliders**: A slider bar (bottom and right) is provided, on which coordinate systems can be zoomed or roamed by mouse dragging.
- **Scroll**: Scrolling inside zooms in on the graph and scrolling out zooms out on the graph.

Tooltip: Displaying data reference to line and axis value under mouse pointer.

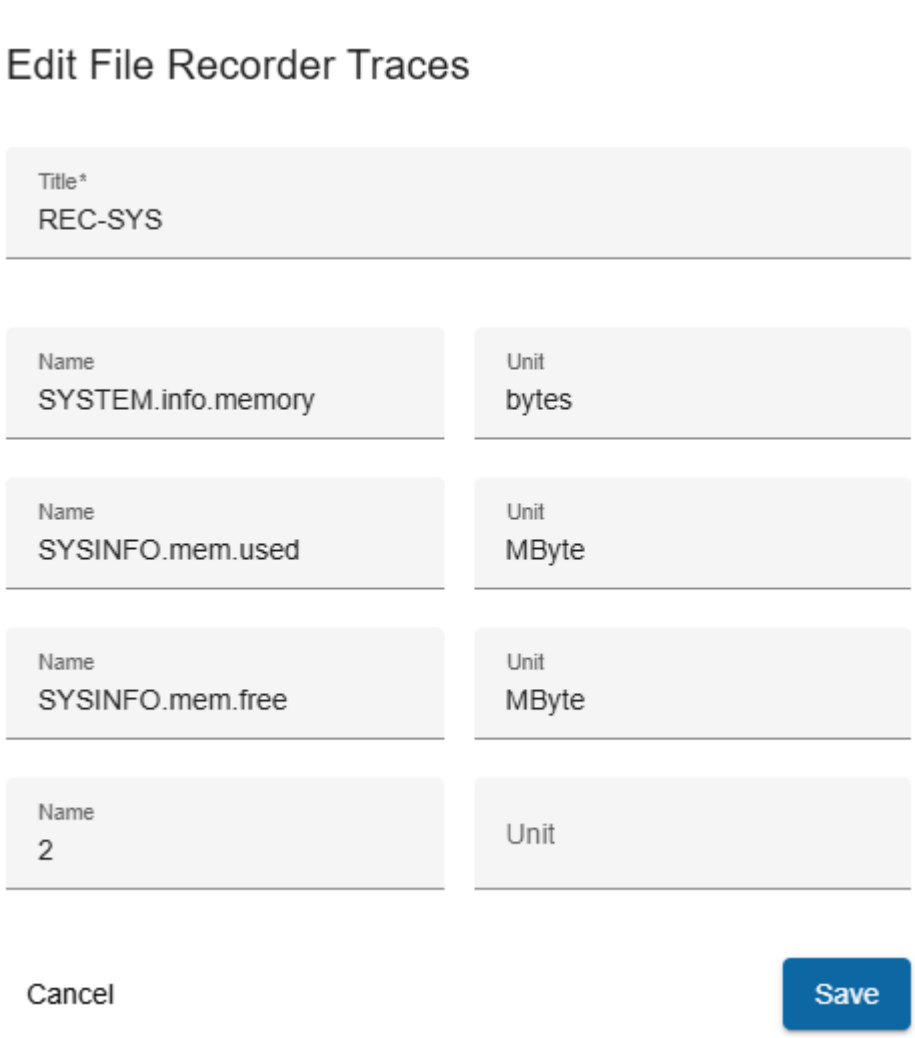
Legends: Clicking on a legend hides or shows the corresponding trace line on the graph for

better visualization.

2.8.2 Dialogs

Open config: Opens a device window config page.

Configure traces



- **Trigger**: when you click on the *Edit traces* button.
- **Fields**:
  - **Title**: The title of selected file-recorder device. *NOTE*: This is differ from device name.
  - **Name**: Free text to set trace name.
  - **Unit**: The unit of trace.
- **Actions**:
  - **Save**:
    - Saves modifications.
    - If an error occurs in the input fields, the button is deactivated.

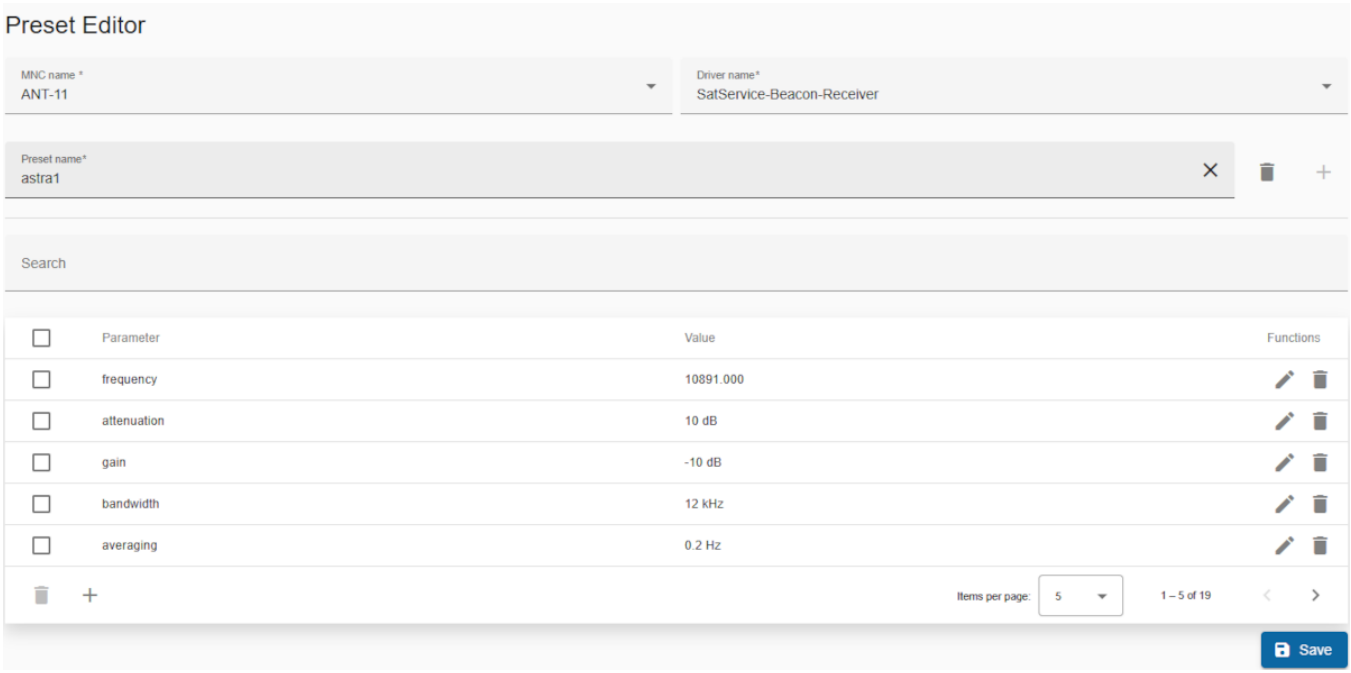
- **Cancel**: Closes the dialog without saving.

2.9 Preset editor

Most sat-nms device drivers allow you to save a snapshot of the device settings in*device preset files* so that the operator can restore these settings at a later time.

The presets are stored on the server that your client programme connects to. In an M&C environment this is the M&C server, in an NMS environment this is the central NMS server. This means that in the latter case, a preset can be saved when operating a VLC and can later be applied to a device on another VLC.

Presets are always assigned to the device type (driver) with which they were recorded. This is because it makes no sense to transfer the settings of a beacon receiver to a DVB encoder. The target device does not *know* what to do with the receiver settings. Even with similar devices (e.g. two IRDs from different manufacturers), there may be differences in the number and type of settings that the devices understand. The software therefore saves the preset files in a structure *by device driver*.



Title: Title of this page.

MNC name: Below the title, you must select an option from the drop-down list.

Driver name: A dropdown with all driver names. Just select from dropdown.

Preset name: Also a dropdown list of preset file names with the search function.

- **Delete**: A *trash can icon* can be used to delete selected preset file.
- **Add preset**: A + button can be used to add Prest. To activate the + button when it is deactivated, simply delete the input of the preset name.

To load a stored preset first you have to select MNC name, then driver name and then preset name. After selection, a table with the saved presets would de displayed, as shown in the image above.

Search bar

- Located at the top of the table.
- Allows users to filter events by keywords.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
    - **Location**: The checkbox column is located at the far left of the table.
    - **Purpose**: Allows users to select one or multiple rows for delete row(s).
    - **Functionality**:
        - **Single Selection**: Click on a single checkbox to select an individual row.
        - **Multiple Selection**: Click multiple checkboxes to select multiple rows at once.
        - **Select all**: The checkbox in the header row allows you to select or deselect all rows on all pages.
        - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **Parameter**: Stored parameter for the preset.
- **Value**: Stored value of parameter.
- **Functions**: Action icons for managing the parameter:
    - **Edit**: Pencil icon to modify/edit the parameter.
    - **Delete**: Trash can icon to delete the parameter.

Bottom toolbar

- **Delete selected rows**: A button to delete selected rows from checkbox column.
- **Create**: + button is used to create new parameter.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

Save: Saves all modifications. *NOTE: You must save the changes before leaving the editor, otherwise the changes will be lost.*

2.9.1 Functionality

Create preset

- Click the + button near the delete icon and preset name input to add a new preset.
- Input the required details.

Create parameter

- Click the + button at the bottom of the table to add a new parameter.
- Input the required details.

Edit parameter

- Click the *pencil icon* in the Functions column to modify parameter details.
- Adjust the settings and save.

Delete preset

- Click the *trash icon* near the preset name input to delete the preset.
- Confirm the action in the pop-up dialog to delete the parameter.

Delete parameter

- Click the *trash icon* in the Functions column to delete an parameter.
- Confirm the action in the pop-up dialog to delete the parameter.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.9.2 Dialogs

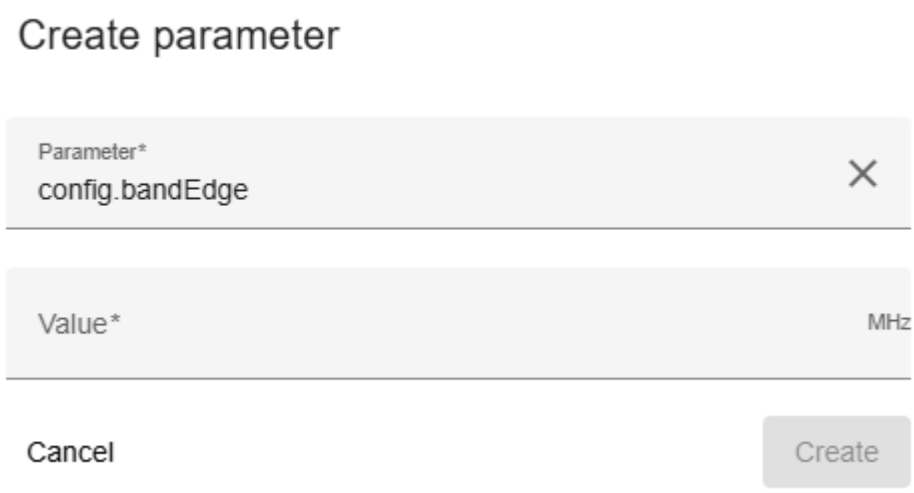
Add preset dialog

- **Trigger**: When you click on the "+" near the delete icon and preset name input to add a

new preset create new preset.

- **Fields**:
  - **Name**: The user defined name of preset. Name must be unique compared to other presets.
- **Actions**:
  - **Add**: Adds the new preset.
  - **Cancel**: Closes the dialog without saving.

Add/edit parameter



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new parameter or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new parameter, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Parameter**: Parameter should be selected from dropdown list. As soon as you have selected a parameter value, the value input will be displayed.
  - **Value**: The parameter value van be added.
- **Actions**:
  - **Create/Save**:
    - For new parameter, this creates the parameter with the provided details.
    - For existing parameter, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

Confirmation dialog

- **Trigger**: Opens when you click the
  - delete preset
  - delete parameter
- **Content**: Asks the user to confirm the action, depending on where you trigger the dialog.
- **Actions**:
  - **Yes**: Confirm the action.
  - **Cancel**: Cancels the action.

2.10 Inventory database

The inventory database provides a structured view of the drivers, so that the user can easily track their state and documents that upload by the user.

The title bar provides access to the two different datasets:

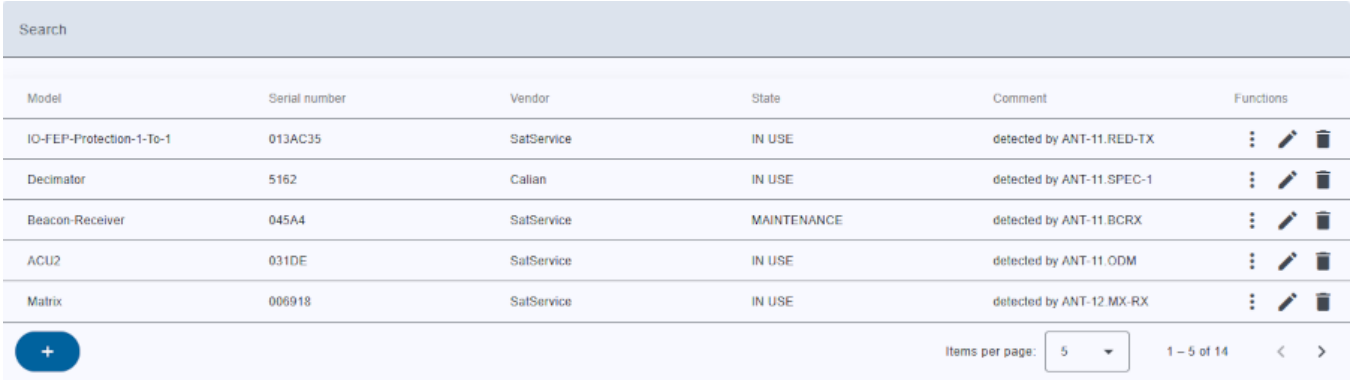
- Inventory (default)
  - displays the list of inventory drivers
- Documents
  - upload document
  - list of uploaded documents

You can switch between these different tables by clicking on the buttons at the top of this page.

On a system without installed SatDB or if the PostgreSQL Database is not reachable an error message will be display: Error DB not reachable. In this case, please check your database installation.

2.10.1 Inventory

The inventory table provides a structured view of the drivers automatically found by M&C or added by the user, so that the user can easily track their state.



To enable the Inventory configure a following in the filevlc.properties with:

- *db.inventory.enabled=true*
- *db.inventory.debug=false*

When the inventory is activated, the M&C automatically recognizes the drivers for whom the serial number has been recognized by M&C and automatically adds them to the database. Non-Recognized driver should be added by the user.

Inventory items are stored by there vendor and model name. For this reason, the item should only exist once.

The Inventory list also contains devices and logs.

- Driver recognized by M&C also check for the devices that are configured on the driver and add to database. If not user can also add manually.
- Logs are also added automatically if M&C has recognized the driver. However, the user can also add the log entry manually. For example, when adding a device that M&C has not recognized automatically. You can see device(s) and logs by clicking on the row of the inventory table.

Search bar

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all list and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

The inventory table contains the following columns:

Column name	Description
Model	name of model
Serial number	Serial number of driver
Vendor	name of vendor
State	State of driver
Comment	Free text describing the situation

The last column located at the far right of the tables provides buttons to run actions on the

corresponding inventory item.

The following functions for inventory are `available` :

Function	Icon	Description
Drop down		Go directs to documents page with selected action.
Edit		modify/edit inventory item
Delete		to delete the inventory item. A confirmation dialog will appear to confirms the action.

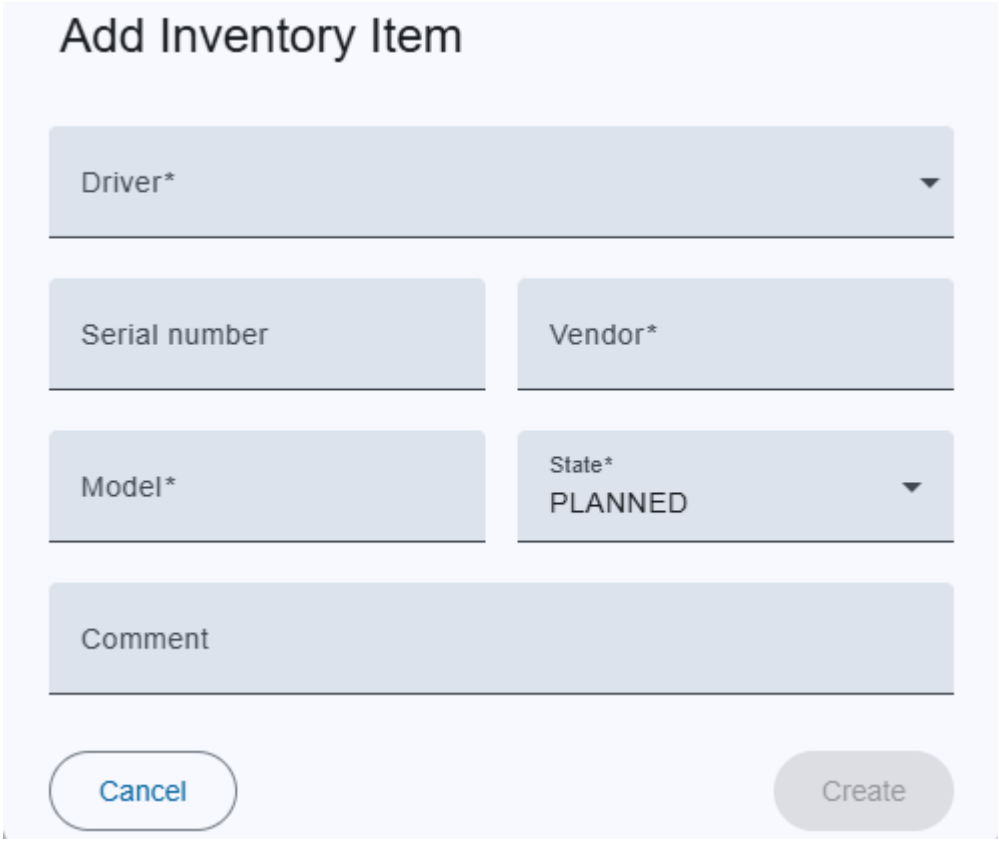
Clicking on a inventory item row shows other relatives tables:

- Devices
- Logs

Bottom toolbar

- **Create**: + button is used to create new inventory item.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

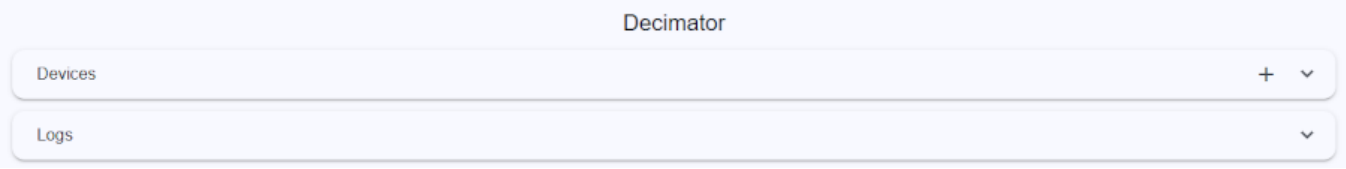
2.10.1.1 Add/edit inventory dialog



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new inventory item or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new inventory item, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Driver**: An drop down with available drivers. Already exists driver in inventory list option is disabled.
  - **Serial number**: Serial number of driver
  - **Vendor**: Manufacture name. Automatically filled if you select an driver but it can also changes.
  - **Model**: Model is driver name.Automatically filled if you select an driver but it can also changes.
  - **State**: State of the driver.
  - **Comment**: Free text for providing some information.
- **Actions**:
  - **Create/Save**:
    - For new inventory item, this creates the inventory item with the provided details.

        - For existing inventory item, this saves modifications.
        - If an error occurs in the input fields, the button is deactivated.
    - **Cancel**: Closes the dialog without saving.

2.10.2 Inventory related tables



Toolbar (top)

- **Title**:
    - Model name
- **Tables**:
    - Devices
    - Logs
    - **Functionality**: Clicking on title or + or arrow to downside expands the table.

2.10.2.1 Devices table

Devices table show the list of devices that are configured on the selected inventory driver. Driver recognized by M&C check for the devices that are configured, add to database. By non-recognized driver devices should be added manually.

Top

- Left-side title of table.
- Plus (+) button to create new device.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon

near the column name.

Table columns

The devices table contains the following columns:

Column name	Description
MNC	Name of M&C in which the device is configured.
Device name	Device name
Online	State of device. If device have an communication fault state will be false else true.

The last column located at the far right of the tables provides buttons to run actions on the corresponding device.

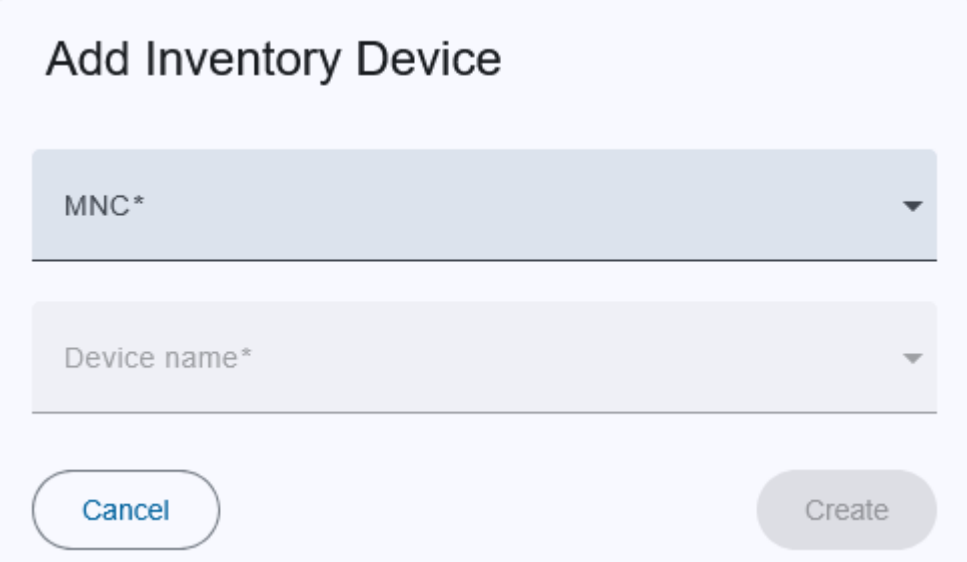
The following functions for device are `available` :

Function	Icon	Description
Edit		modify/edit device
Add log		Opens Add Inventory Log dialog with prefilled data to add a log in inventory database.
Delete		to delete the device. A confirmation dialog will appear to confirms the action.

Bottom toolbar

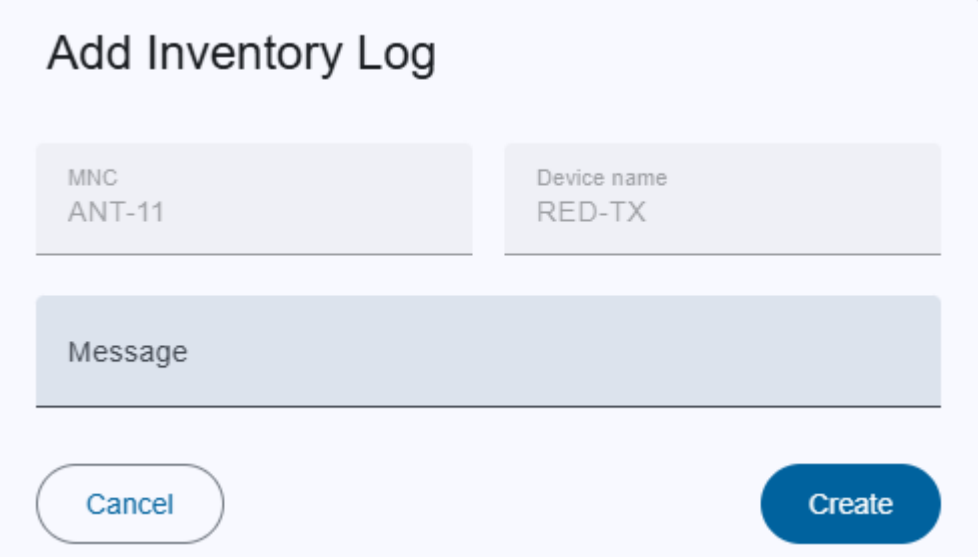
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.10.2.2 Add/edit device dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit device in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **MNC**: Name of the M&C.
  - **Device name**: Once you selected the M&C device list will be available on behalf of selected M&C and selected Driver of inventory item.
- **Actions**:
  - **Create/Save**:
    - For new device, this creates the device with the provided details.
    - For existing device, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

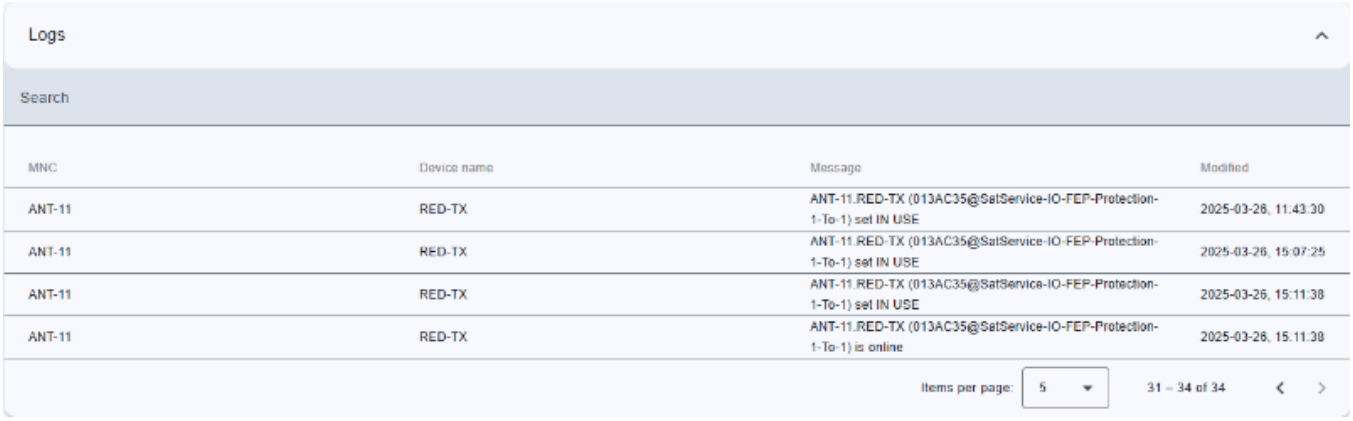
2.10.2.3 Add log dialog



- **Trigger**:
  - when you click on the button on the device column
- **Fields**:
  - **MNC**: Name of the M&C.
  - **Device name**: Device name.
  - **Message**: A short message that shows the purpose of this log.
- **Actions**:
  - **Create**:
    - this created a new log.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

2.10.2.4 Logs table

The logs helps to trace the activities of device(s) and driver. Logs are also added automatically if M&C has recognized the driver. However, the user can also add the log entry manually. For example, when adding a device that M&C has not recognized automatically.



Top

- Left-side title of table.
- Icon button to expand or collapse table

Search bar

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all list and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

The Logs table contains the following columns:

Column name	Description
MNC	Name of M&C.
Device name	Device name.
Message	Purpose of this log.
Modified	Date of added log.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.11 Documents

In Inventory database you can also upload documents and download documents. Documents can be attached to M&C, Driver or Globally.

Expand All: Expand all category tables.

Import file: Import file trigger *Upload document* dialog.

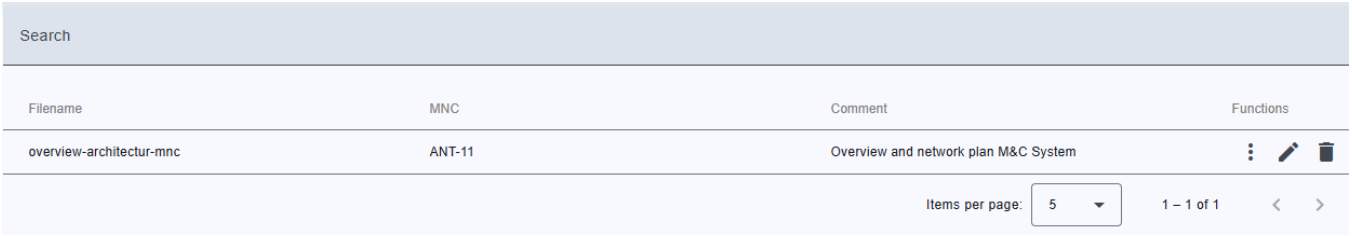
Global : If the document is uploaded without M&C or driver name, it belongs to Global category.

MNC : If the document is uploaded with, it belongs to MNC category.

Driver : If the document is uploaded with driver name, it belongs to Driver category.

Tables

The tables for Global, MNC and Driver are identical.



Search bars

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all list and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

The document table contains the following columns:

Column name	Description
Filename	Name of M&C.
MNC/Driver	Depending which section you expanded MNC/Driver will shown.
Comment	Purpose of document.

The last column located at the far right of the tables provides buttons to run actions on the corresponding inventory item.

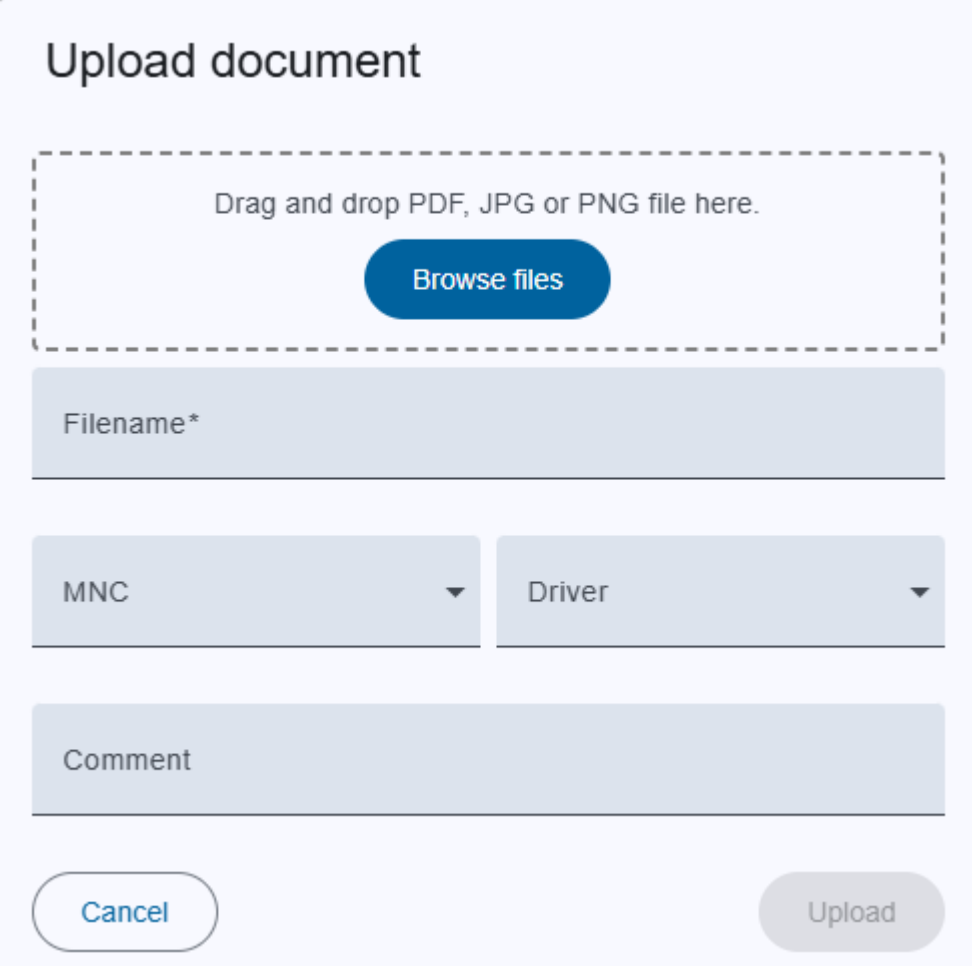
The following functions for inventory are `available` :

Function	Icon	Description
Drop down		Shows the option to download document or open document in new tab.
Edit		modify/edit document item
Delete		to delete the document. A confirmation dialog will appear to confirms the action.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.11.1 Upload/edit document



- **Trigger**:
  - when you click on the "upload" button on the top toolbar to upload or
  - from drop down ⋮ "Upload file" or
  - an on *pencil icon* to edit document in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **File**: You can just drop the file in section or just browse the files by clicking on "Browse files". Supported format are *pdf, png, jpg*.
  - **Filename**: Once you selected the file or dropped the file, filename will be taken from dropped file. Can also be changed.
  - **MNC**: M&C name to whom document belongs. If driver name is selected M&C input will be disabled.
  - **Driver**: Driver name to whom document belongs. If M&C name is selected M&driver input will be disabled.
  - **Comment**: Some information about document.

NOTE: If M&C and Driver fields are empty, the document will belongs to*Global Category*.

Edit document: If you want to change the document properties but do not want to upload the document, you do not need to drop or browse the "File" section.

- **Actions**:
  - **Upload**:
    - this upload document.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

2.12 Satellite database

The Satellite database provides a structured view of satellites, operators, and antennas. Each category is represented by a distinct table. Users can navigate between these tables using the menu options and access additional details for a selected satellite.

The title bar provides access to the three different datasets:

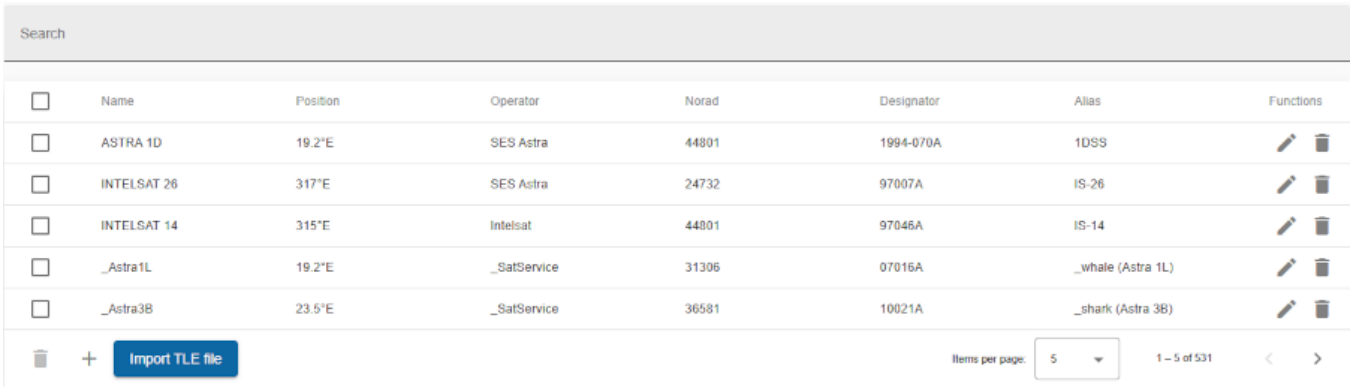
- Satellites (default)
  - displays the list of satellites stored in the database
- Satellite operators
  - each satellite belongs to an satellite operator
  - here you can store for example contact information for line-ups
- Antennas
  - list of configured antennas (and the related devices) which should use the database
  - here you defined the satellite positions an antenna can use to point to a satellite

You can switch between these different tables by clicking on the buttons at the top of this page.

On a system without installed SatDB or if the PostgreSQL Database is not reachable an error message will be display: Error DB not reachable. In this case, please check your database installation.

2.12.1 Satellite list

This shows the list of all satellites in the database.



Satellites are stored by there unique name. We recommend to use the names used by CelesTrak, because this allowes easy bulk import of TLE (two-Line elements). If you prefere deferent name, use the optional Alias field.

The satellite list itself does not contain any satellite position because they depends on the individual antenna. These positions can be found on the Antenna list page.

To use this satellites to move antennas you have to configure the corresponding Antenna Management Devices on the MNC server(s) which controlls the ACU (antenna control unit):

- Antenna-Management

Search bars

- Located at the top of the table.
- Allows users to filter by:
  - *Keywords*: full-text search over all channels and all columns

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

The first column located at the far left of the table provides a checkbox to select one or more channels (rows) and perform the same operation on all selected channels.

- **Single Selection**: Click on a single checkbox to select an individual satellite
- **Multiple Selection**: Click multiple checkboxes to select multiple satellite.
- **Select all**: The checkbox in the header row allows you to select or deselect all satellites on all pages.

The following function(s) are available:

Function	Icon	Description

Function	Icon	Description
delete		delete the selected satellite from the database

The last column located at the far right of the tables provides buttons to run actions on the corresponding satellite.

The following functions for managing a satellite are `available` :

Function	Icon	Description
Delete		to delete the satellite
Edit		modify/edit satellite

The following buttons for global function(s) are available at the the bottom of the table:

Function	Icon	Description
Add		add a new satellite
Delete		to delete all selected the satellite
Import	Import TLE file	[import TLE] data from file
Page	Pagination controls	set the number of items displayed per page (e.g., 5, 10, or 25) and navigate between pages

The satellite table contains the following columns:

Column name	Description
Name	name of satellite
Position	satellite orbit position in degrees
Operator	name of satellite operator
Norad number	NORAD Catalog Number
Designator	International Designator
Alias	Customized alias name

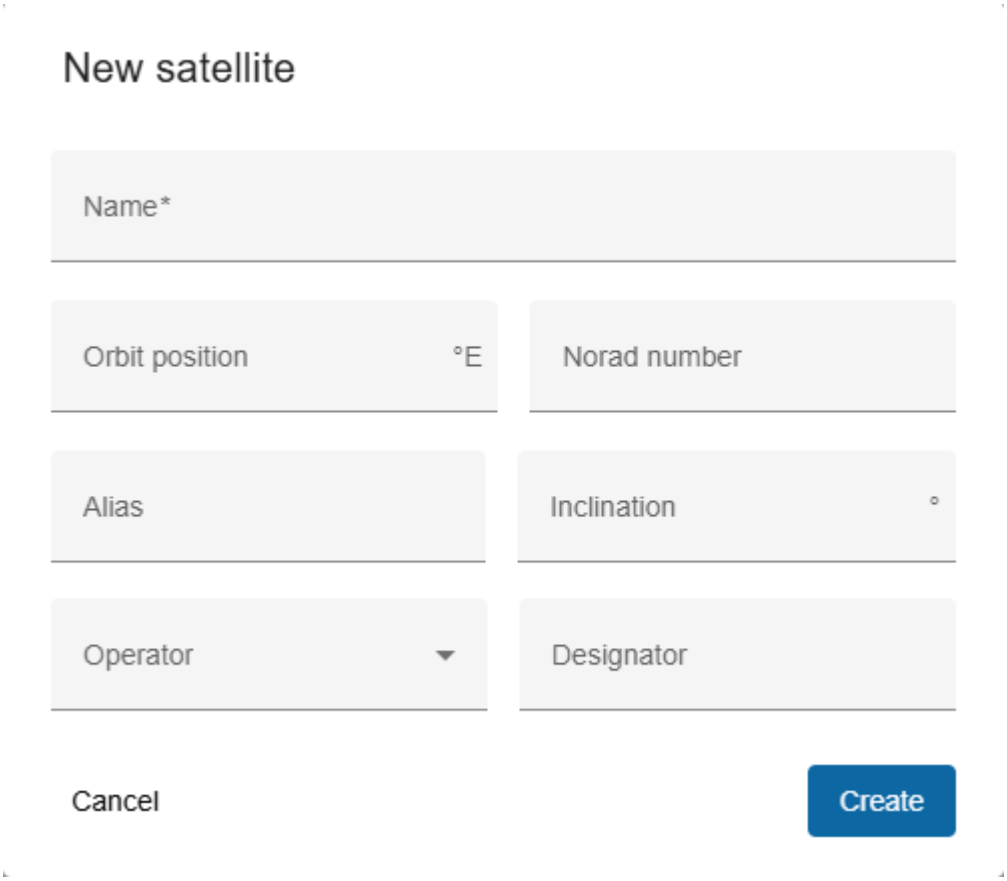
Clicking on a satellite row shows other relatives tables:

- Satellite position
- I11
- Beacons
- TC channels
- TM channels of selected row

Bottom toolbar

- **Create**: + button is used to create new satellite.
- **Import TLE file**: Opens a dialog to import TLE parameters.

2.12.2 Add/edit satellite dialog



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new satellite or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new satellite, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Name**: The user defined name of this satellite.
  - **Orbit position**: Satellite orbit position in degrees.

- **Norad number**: unique name (world wide standardized)
- **Alias**: This can be used by customer to add own name.
- **Inclination**: Satellite inclination in degrees.
- **Operator**: Add satellite operator.
- **Designator**: Unique name (world wide standardized).

- **Actions**:
  - **Create/Save**:
    - For new satellite, this creates the satellite with the provided details.
    - For existing satellite, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

2.12.2.1 On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column or trash icon from bottom toolbar.
- **Content**: Asks the user to confirm whether they want to delete the selected satellite(s).
- **Actions**:
  - **Yes**: Deletes the satellite(s) permanently.
  - **Cancel**: Cancels the deletion action.

2.12.3 Satellite related tables

Toolbar (top)

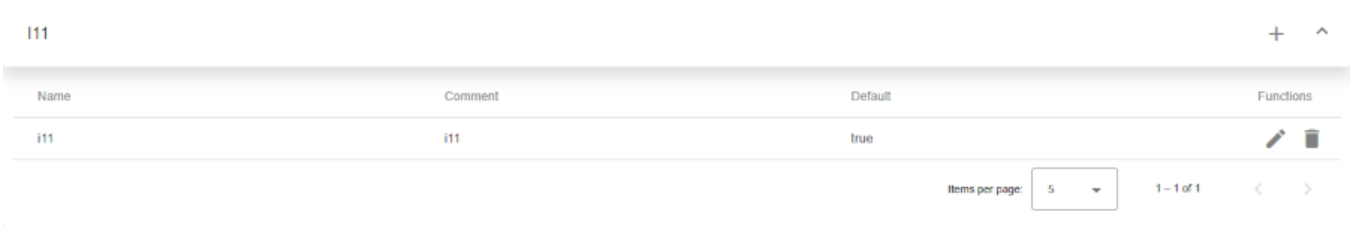
- **Title**:
  - Satellite name
  - Satellite alias
- **Edit NORAD TLE**: Trigger dialog to modify NORAD TLE.

Tables:

- I11 table
- Beacons
- TC channels
- TM channels
- **Functionality**: Clicking on title or + or arrow to downside expands the table.

2.12.3.1 I11 table

Intelsat 11 elements describing the satellite path for a given time. It is comparable to TLE (Two-Line Elements) but it is possible to have multiple I11 elements per satellite for the same time but with different accuracy. It may be useful to store very accurate I11 elements but they are only valid for a short time and in case that you are not able to update regularly, you can store a long term I11 in the database to be prepared if the short term element is expired.



Top

- Left-side title of table.
- Plus (+) button to create new i11.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Name**: The name of the satellite as stated in the original I11 parameter set.
- **Default**: True means this is the default I11 dataset for this satellite.
- **Comment**: Describing the purpose of this dataset.
- **Functions**: Action icons for managing the key:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.12.3.1.1 Functionality

Create i11

- Click the + button at the top of the table to add a new i11.
- Input the required details.

Edit i11

- Click the *pencil icon* in the Functions column to modify i11 details.
- Adjust the settings and save.

Delete i11

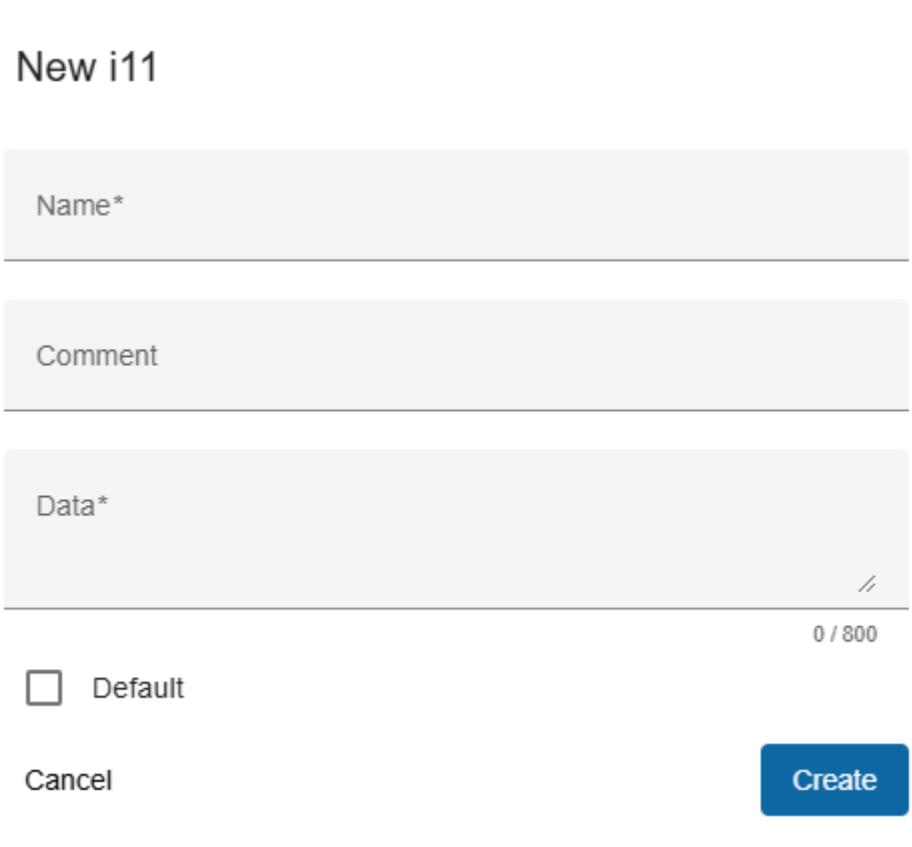
- Click the *trash icon* in the Functions column to delete an i11.
- Confirm the action in the pop-up dialog to delete the i11.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.12.3.1.2 Dialogs

Add/edit i11 dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit i11 in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:

- **Name**: The name of the satellite as stated in the original I11 parameter set.
- **Comment**: Free text describing the purpose of this dataset.
- **Norad number**: unique name (world wide standardized)
- **Data**: The 11 ephemeris parameters, floating point, separated by semicolon characters.
- **Default**: Set i11 as default.

- **Actions**:

  - **Create/Save**:
    - For new i11, this creates the satellite with the provided details.
    - For existing i11, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected i11.
- **Actions**:
  - **Yes**: Deletes the i11 permanently.
  - **Cancel**: Cancels the deletion action.

2.12.3.2 Beacons table

Satellite beacons are used to track satellites. Each satellite can have more than one beacon, usually there are at least one beacons on every polarization. The preferred beacon can be marked as default in the database. It will be used if the operator does not select a specific beacon for Step-Track.

Top

- Left-side title of table.
- Plus (+) button to create new beacon.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Frequency**: Beacon frequency, floating point, MHz.
- **Polarization**: This is an enumeration.
- **Comment**: Describing the purpose of this beacon.
- **Default**: True means this is the default beacon dataset for this satellite. .**Attenuation**: Modify attenuation value stored in the database for one particular pair of antenna and beacon. Opens beacon-attenuation dialog.
- **Functions**: Action icons for managing the key:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.12.3.2.1 Functionality

Create beacon

- Click the + button at the top of the table to add a new beacon.
- Input the required details.

Edit beacon

- Click the *pencil icon* in the Functions column to modify beacon details.
- Adjust the settings and save.

Attenuation

- Click *pencil outlined* in the row under attenuation. Modify value stored in the database for one particular pair of antenna and beacon. Opens beacon-attenuation dialog.

Delete beacon

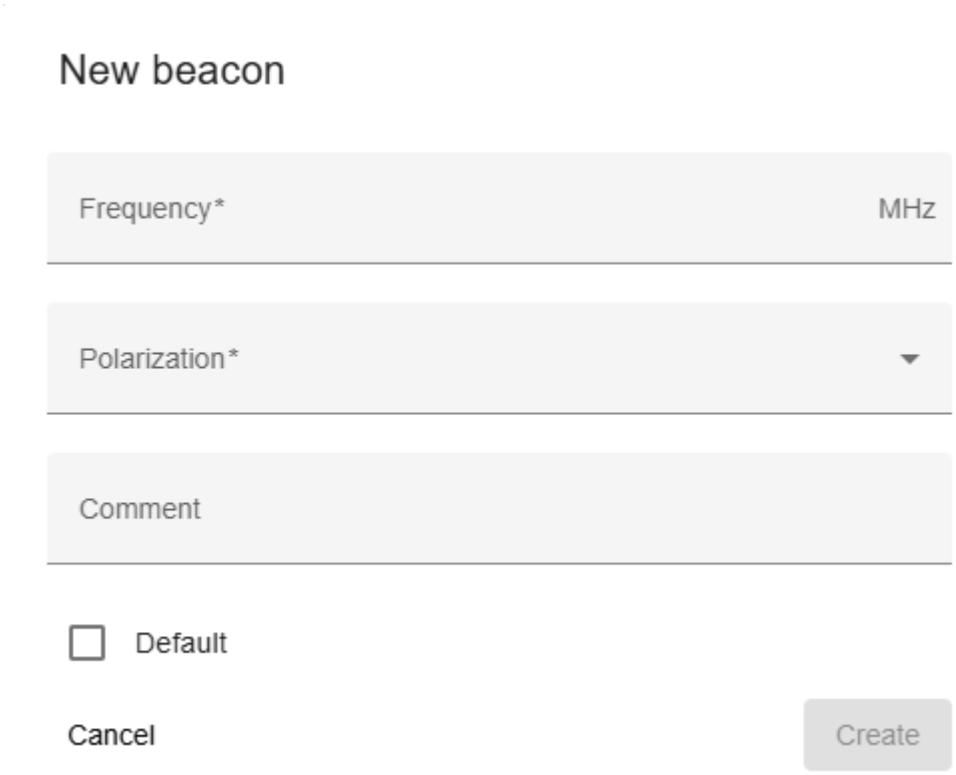
- Click the *trash icon* in the Functions column to delete an beacon.
- Confirm the action in the pop-up dialog to delete the beacon.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.12.3.2.2 Dialogs

Add/edit beacon dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit beacon in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Frequency**: Beacon frequency, floating point, MHz.
  - **Polarization**: An enumeration, one of "H", "V", "RHCP" or "LHCP".
  - **Comment**: Free text describing the purpose of this dataset.
  - **Default**: Set beacon as default.
- **Actions**:
  - **Create/Save**:
    - For new beacon, this creates the beacon with the provided details.
    - For existing beacon, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

Modify beacon attenuation

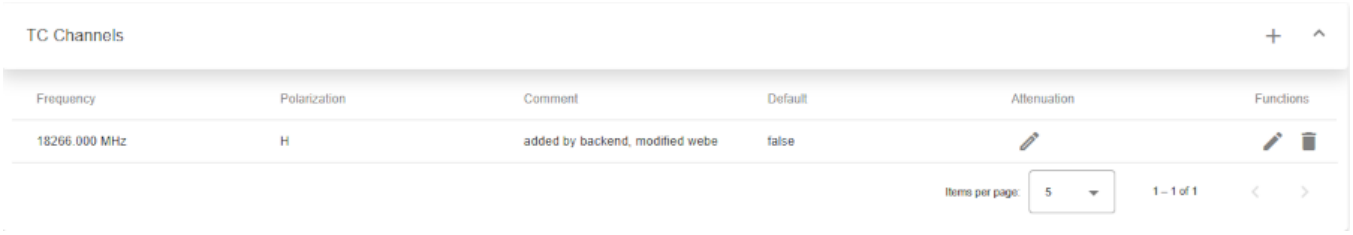
- **Trigger**: Click on the *pencil outlined* button in the row under *attenuation*
- **Fields**:
  - **Select antenna**: Drop-down to select antenna.
  - **Attenuation**: Receiver attenuation, floating point, dB.
- **Actions**:
  - **Save**:
    - Saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected beacon.
- **Actions**:
  - **Yes**: Deletes the beacon permanently.
  - **Cancel**: Cancels the deletion action.

2.12.3.3 TC channel table

Tele-Command (TC) channels defining communcation channels used to send commands to a satellite.



Top

- Left-side title of table.
- Plus (+) button to create new TC channel.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Frequency**: TC channel frequency, floating point, MHz.
- **Polarization**: This is an enumeration.
- **Comment**: Describing the purpose of this beacon.
- **Default**: True means this is the default beacon dataset for this satellite. .**Attenuation**: Modify attenuation value stored in the database for one particular pair of antenna and TC channel. Opens TC-Attenuation dialog.
- **Functions**: Action icons for managing the key:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.12.3.3.1 Functionality

Create TC channel

- Click the + button at the top of the table to add a new TC channel.
- Input the required details.

Edit TC channel

- Click the *pencil icon* in the Functions column to modify TC channel details.
- Adjust the settings and save.

Attenuation

- Click *pencil outlined* in the row under attenuation. Modify value stored in the database for one particular pair of antenna and TC channel. Opens beacon-attenuation dialog.

Delete TC channel

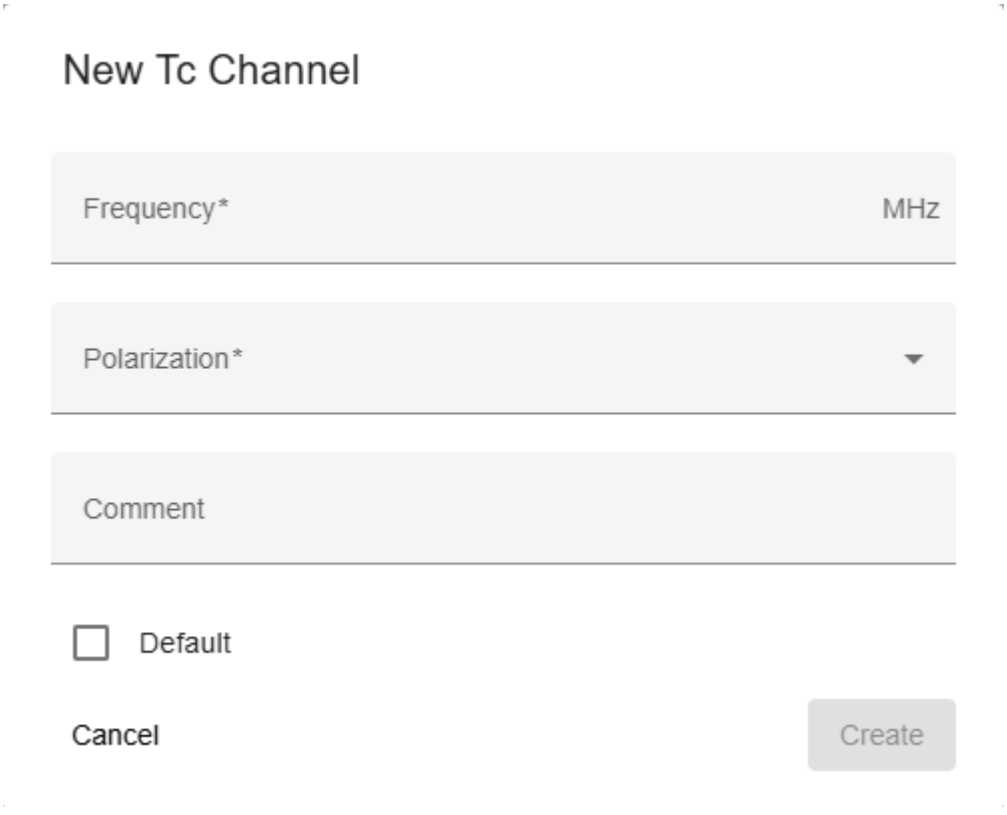
- Click the *trash icon* in the Functions column to delete an TC channel.
- Confirm the action in the pop-up dialog to delete the TC channel.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.12.3.3.2 Dialogs

Add/edit TC channel dialog

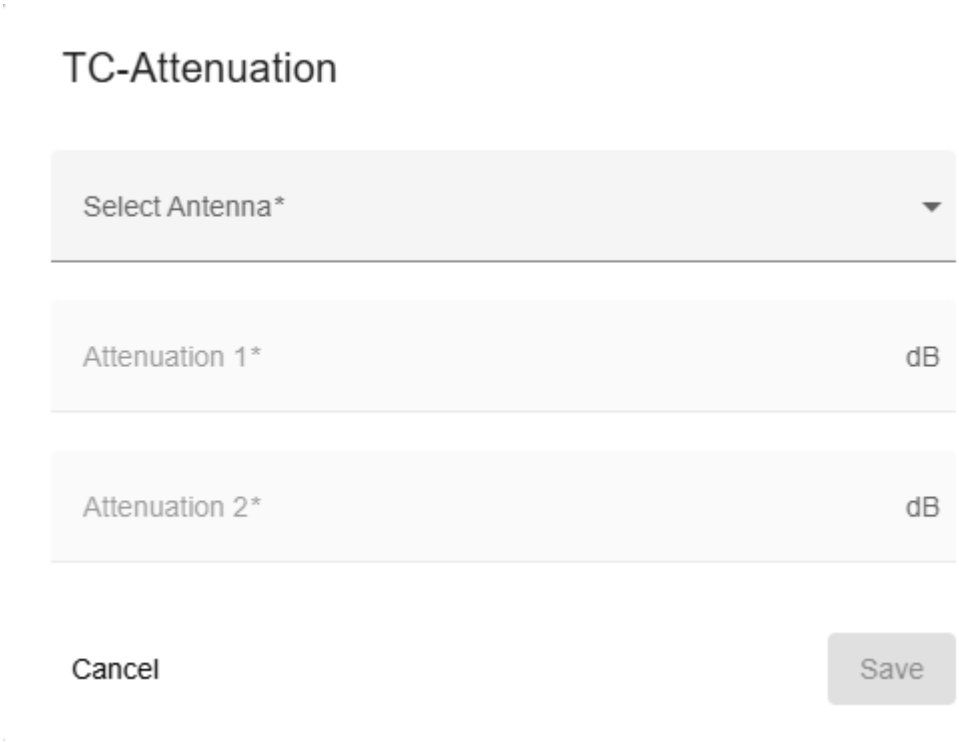


- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit TC channel in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:

- **Frequency**: TC channel frequency, floating point, MHz.
- **Polarization**: An enumeration, one of "H", "V", "RHCP" or "LHCP".
- **Comment**: Free text describing the purpose of this dataset.
- **Default**: Set TC channel as default.

- **Actions**:
  - **Create/Save**:
    - For new TC channel, this creates the TC channel with the provided details.
    - For existing TC channel, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

Modify TC channel attenuation



- **Trigger**: Click on the *pencil outlined* button in the row under *attenuation*
- **Fields**:
  - **Select antenna**: Drop-down to select antenna.
  - **Attenuation 1**: Transmit attenuation1, floating point, dB.
  - **Attenuation 2**: Transmit attenuation2, floating point, dB.
- **Actions**:
  - **Save**:
    - Saves modifications.
    - If an error occurs in the input fields, the button is deactivated.

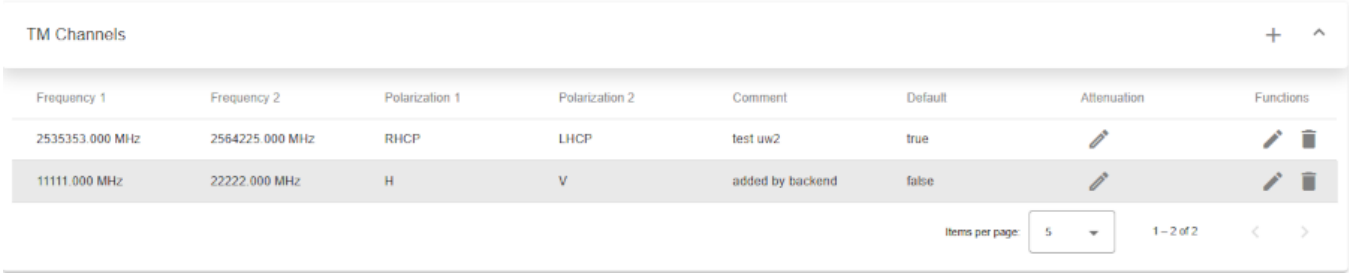
- **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected TC channel.
- **Actions**:
  - **Yes**: Deletes the TC channel permanently.
  - **Cancel**: Cancels the deletion action.

2.12.3.4 TM channel table

Telemetry (TM) channels defining communcation channels used to receive status and measurement data from satellites.



Top

- Left-side title of table.
- Plus (+) button to create new TM channel.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Frequency 1**: Primary receive frequency, floating point, MHz.
- **Frequency 2**: Secondary receive frequency, floating point, MHz.
- **Polarization 1**: This is an enumeration.
- **Polarization 2**: This is an enumeration.
- **Comment**: Describing the purpose of this beacon.
- **Default**: True means this is the default TM channel dataset for this satellite. .
  Attenuation: Modify attenuation value stored in the database for one particular pair of antenna and TM channel. Opens TC-Attenuation dialog.
- **Functions**: Action icons for managing the key:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.12.3.4.1 Functionality

Create TM channel

- Click the + button at the top of the table to add a new TM channel.
- Input the required details.

Edit TC channel

- Click the *pencil icon* in the Functions column to modify TC channel details.
- Adjust the settings and save.

Attenuation

- Click *pencil outlined* in the row under attenuation. Modify value stored in the database for one particular pair of antenna and TC channel. Opens beacon-attenuation dialog.

Delete TC channel

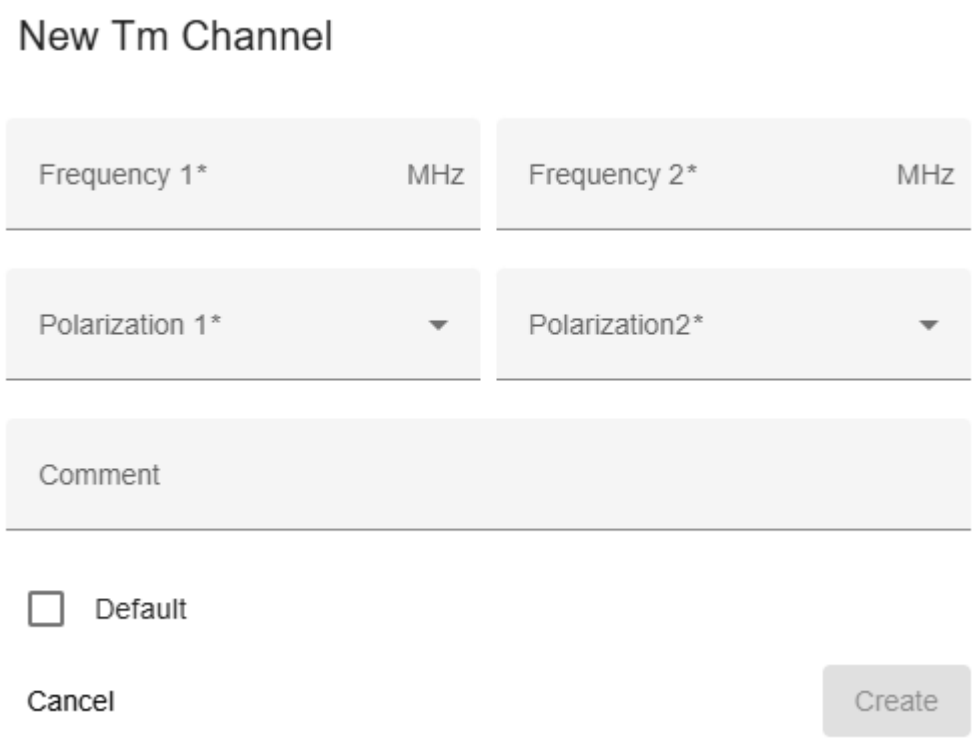
- Click the *trash icon* in the Functions column to delete an TC channel.
- Confirm the action in the pop-up dialog to delete the TC channel.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

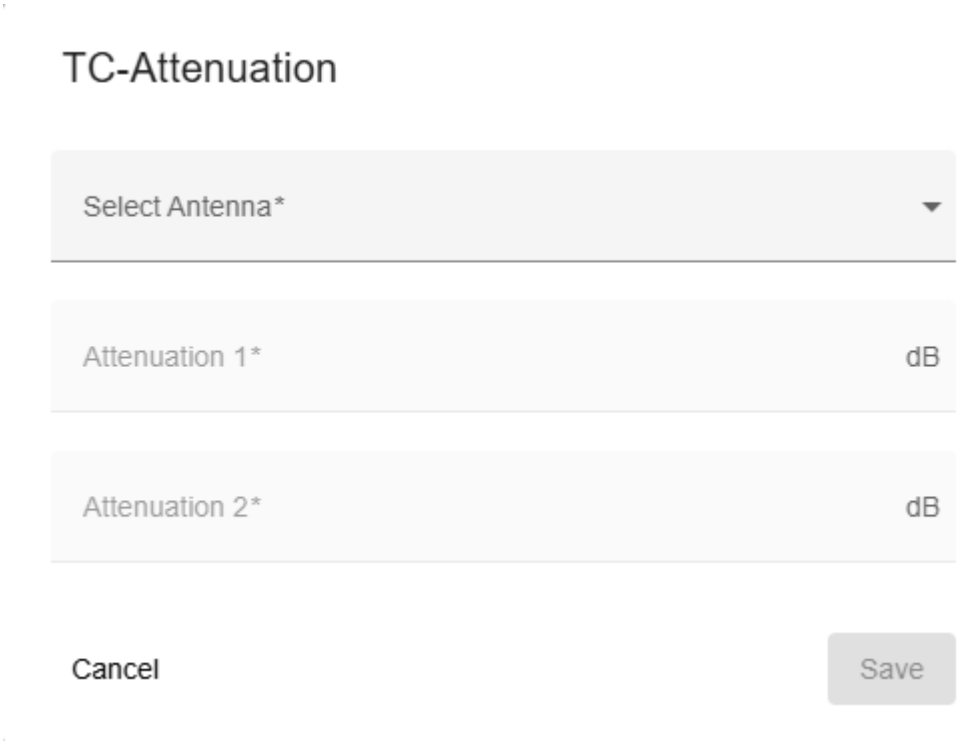
2.12.3.4.2 Dialogs

Add/edit TC channel dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit TC channel in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Frequency 1**: Primary receive frequency, floating point, MHz.
  - **Frequency 2**: Secondary receive frequency, floating point, MHz.
  - **Polarization 1**: This is an enumeration.
  - **Polarization 2**: This is an enumeration.
  - **Comment**: Free text describing the purpose of this dataset.
  - **Default**: Set TM channel as default.
- **Actions**:
  - **Create/Save**:
    - For new TM channel, this creates the TC channel with the provided details.
    - For existing TM channel, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

Modify TM channel attenuation



- **Trigger**: Click on the *pencil outlined* button in the row under *attenuation*
- **Fields**:
  - **Select antenna**: Drop-down to select antenna.
  - **Attenuation 1**: Transmit attenuation1, floating point, dB.
  - **Attenuation 2**: Transmit attenuation2, floating point, dB.
- **Actions**:
  - **Save**:
    - Saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

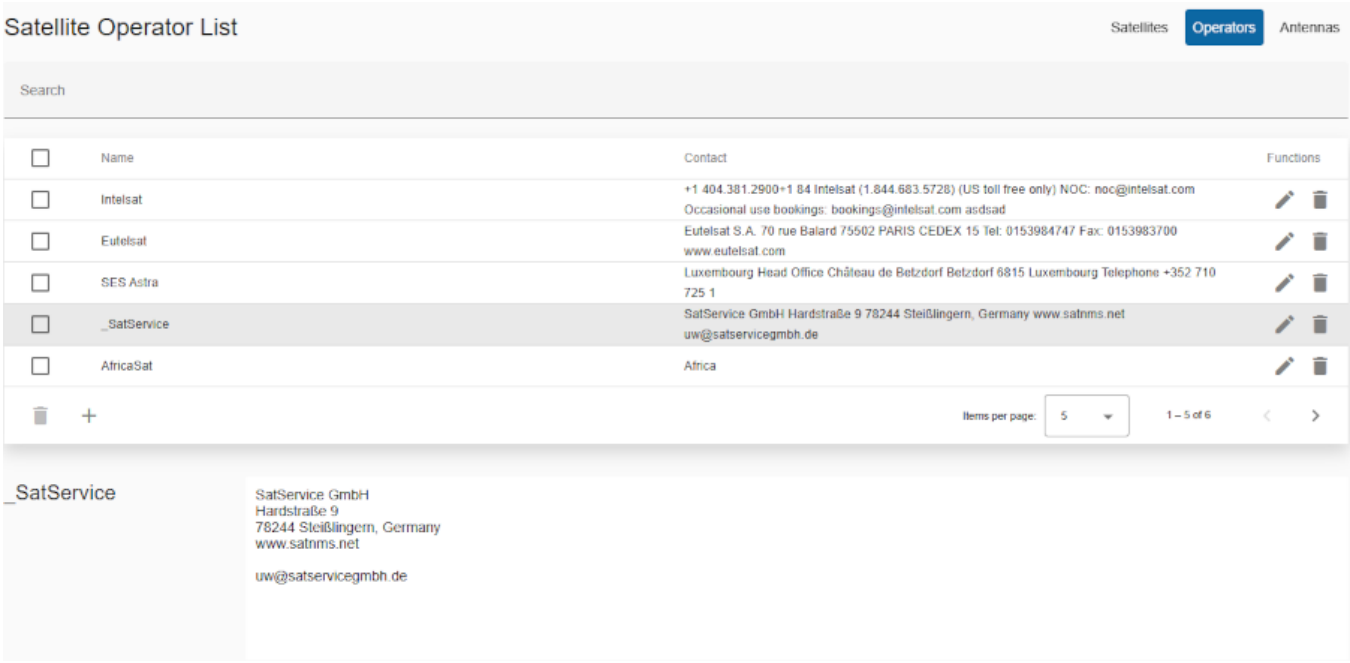
On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected TC channel.
- **Actions**:
  - **Yes**: Deletes the TC channel permanently.
  - **Cancel**: Cancels the deletion action.

2.13 Satellite operator list

All satellites operators known to system. You need to define a satellite operator before you can create an new satellite.

This list is also useful to store contact information of an satellite operator, e.g to perform a line-up before your start a transmission.



Title: Title of selected table (e.g. Operator list).

Menu options:

- **Satellites**: Displays the table of satellites.
- **Operators**: Displays the table of operators. The selected option has background color.
- **Antennas**: Displays the table of antennas.

Search bar

- Located at the top of the table.
- Allows users to filter events by keywords.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
  - **Location**: The checkbox column is located at the far left of the table.
  - **Purpose**: Allows users to select one or multiple rows for delete row(s).
  - **Functionality**:
    - **Single Selection**: Click on a single checkbox to select an individual row.
    - **Multiple Selection**: Click multiple checkboxes to select multiple rows at

once.
    - **Select all**: The checkbox in the header row allows you to select or deselect all rows on all pages.
    - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **Name**: The name of operator.
- **Contact**: Contact details of operator.
- **Functions**: Action icons for managing the operator:
    - **Edit**: Pencil icon to modify/edit the operator.
    - **Delete**: Trash can icon to delete the operator.

Rows: Clicking on operator row shows details of selected row (operator).

Bottom toolbar

- **Delete selected rows**: A button to delete selected rows from checkbox column.
- **Create**: + button is used to create new operator.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

Details of selected operator:

- Name of operator
- Contact details of operator

2.13.1 Functionality

Create operator

- Click the + button at the bottom of the table to add a new operator.
- Input the required details.

Edit operator

- Click the *pencil icon* in the Functions column to modify operator details.
- Adjust the settings and save.

Delete operator

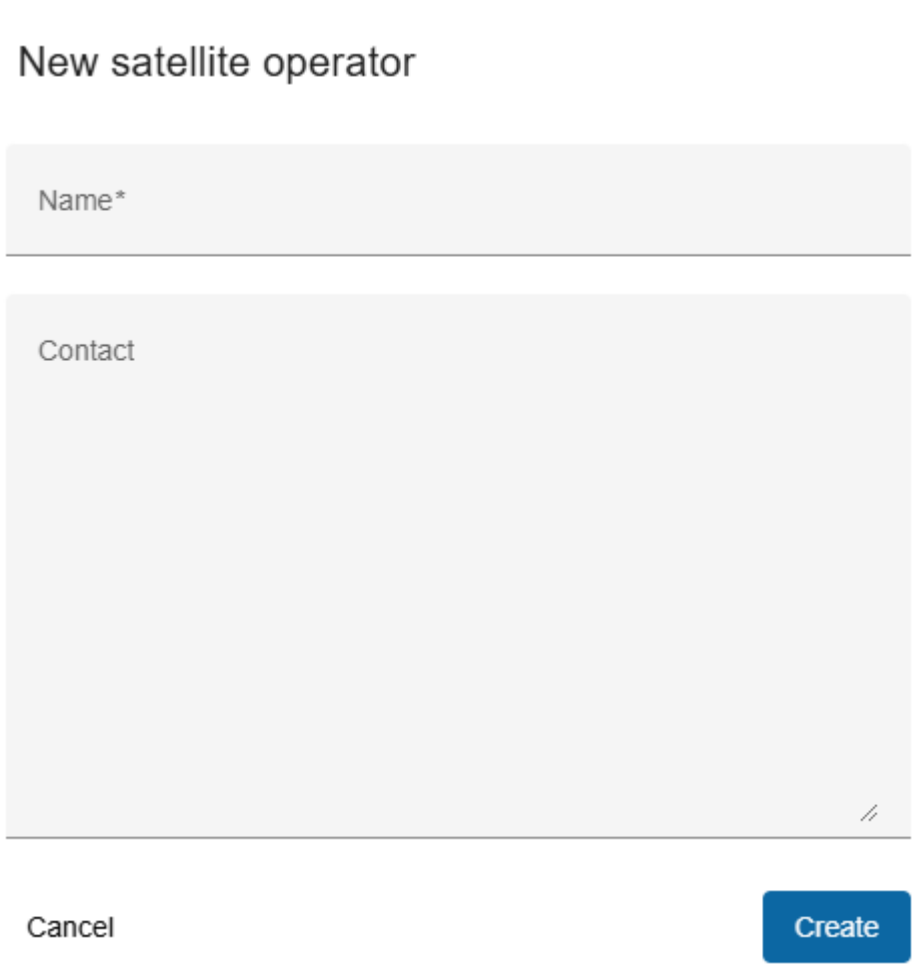
- Click the *trash icon* in the Functions column to delete an operator.
- Confirm the action in the pop-up dialog to delete the operator.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.13.2 Dialogs

Add/edit satellite dialog



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new operator or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new operator, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Name**: The user defined name of this operator.
  - **Contact**: Contact details of operator.
- **Actions**:
  - **Create/Save**:
    - For new operator, this creates the operator with the provided details.
    - For existing operator, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

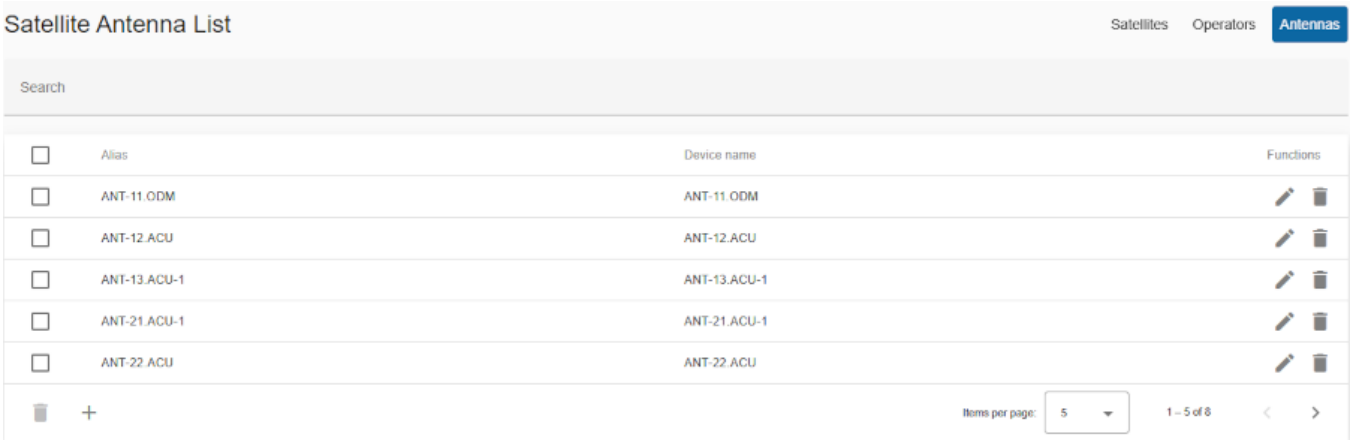
- **Trigger**: Opens when you click the trash icon for an operator from menu column or trash icon from bottom toolbar .
- **Content**: Asks the user to confirm whether they want to delete the selected operator(s).
- **Actions**:
  - **Yes**: Deletes the operator(s) permanently.
  - **Cancel**: Cancels the deletion action.

2.14 Antenna list

All saved antenna in database.

The position of a satellite (Azimuth, Elevation, Polarization) depends on the geographically location of the antenna and structural conditions of the antenna. Therefore a satellite position is different for every antenna.

With this list you define all antennas managed by this M&C system and which satellites are reachable with this antenna. To add a new satellite, your have to create the satellite before you can add here the position.



Title: Title of selected table (e.g. Antenna list).

Menu options:

- **Satellites**: Displays the table of satellites.
- **Operators**: Displays the table of operators.
- **Antennas**: Displays the table of antennas. The selected option has background color.

Search bar

- Located at the top of the table.
- Allows users to filter events by keywords.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.

- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
  - **Location**: The checkbox column is located at the far left of the table.
  - **Purpose**: Allows users to select one or multiple rows for delete row(s).
  - **Functionality**:
    - **Single Selection**: Click on a single checkbox to select an individual row.
    - **Multiple Selection**: Click multiple checkboxes to select multiple rows at once.
    - **Select all**: The checkbox in the header row allows you to select or deselect all rows on all pages.
    - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **Alias**: Alias of antenna.
- **Device name**: Device name from the MNC system.
- **Functions**: Action icons for managing the antenna:
  - **Edit**: Pencil icon to modify/edit the antenna.
  - **Delete**: Trash can icon to delete the antenna.

Rows: Clicking on antenna row shows other relatives tables like Satellite positions and Tracks of selected row.

Bottom toolbar

- **Delete selected rows**: A button to delete selected rows from checkbox column.
- **Create**: + button is used to create new antenna.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.14.1 Functionality

Create antenna

- Click the + button at the bottom of the table to add a new antenna.
- Input the required details.

Edit antenna

- Click the *pencil icon* in the Functions column to modify antenna details.
- Adjust the settings and save.

Delete antenna

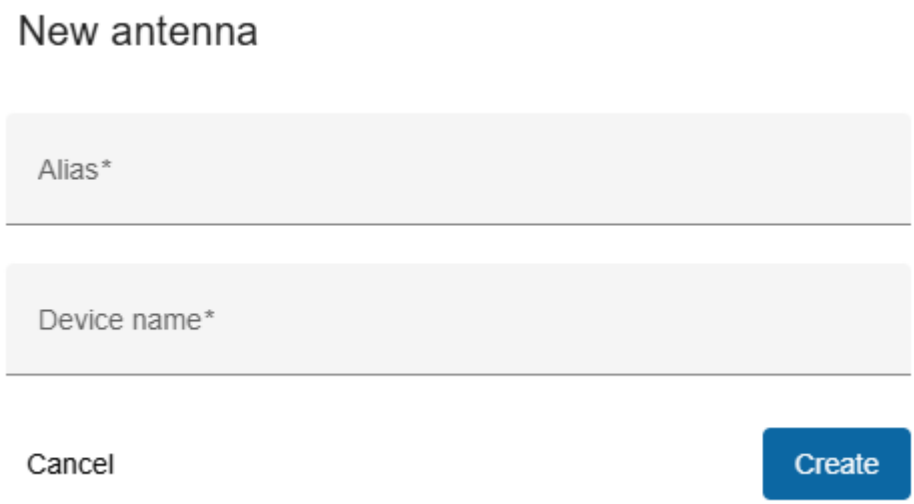
- Click the *trash icon* in the Functions column to delete an antenna.
- Confirm the action in the pop-up dialog to delete the antenna.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.14.2 Dialogs

Add/edit satellite dialog



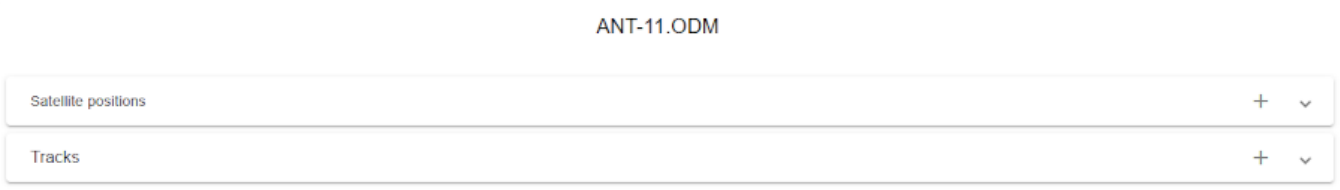
- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new antenna or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new antenna, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Alias**: Free text, can be used by user to add own name.
  - **Device name**: Free text, device name from the MNC system.
- **Actions**:
  - **Create/Save**:
    - For new antenna, this creates the antenna with the provided details.
    - For existing antenna, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an antenna from menu column or trash icon from bottom toolbar .
- **Content**: Asks the user to confirm whether they want to delete the selected antenna(s).
- **Actions**:
  - **Yes**: Deletes the antenna(s) permanently.

- **Cancel**: Cancels the deletion action.

2.14.3 Antenna related tables



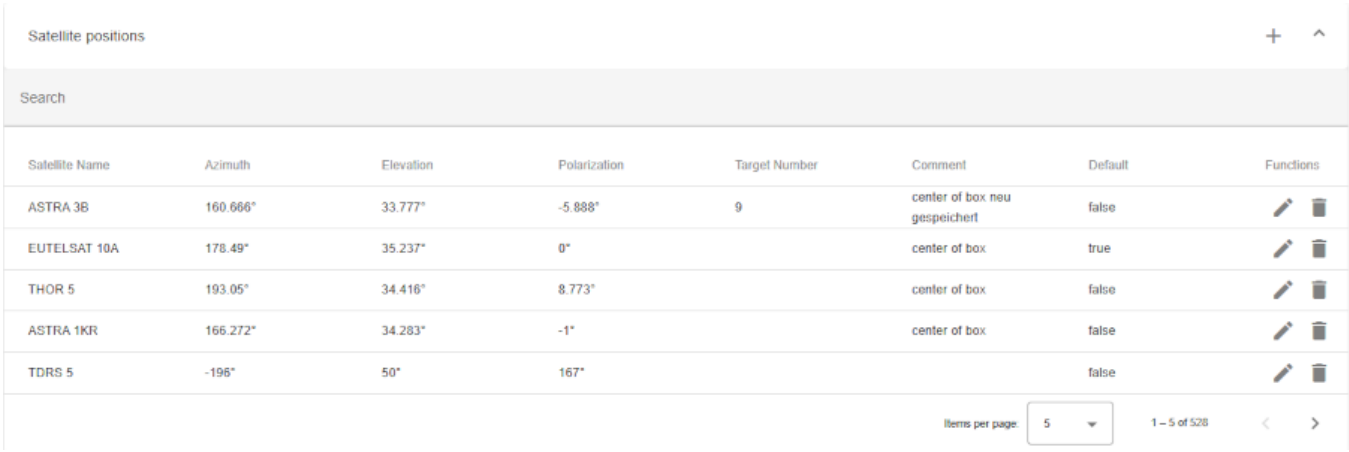
Title: Antenna name

Tables:

- Satellite position
- Tracks
- Import targets from Antenna Controller
- **Functionality**: Clicking on title or + or arrow to downside expands the table.

2.14.3.1 Satellite position table

The list of all satellite positions for the given antenna.



Top

- Left-side title of table.
- Plus (+) button to create new satellite position.
- Icon button to expand or collapse table

Search bar

- Located at the top of the table.
- Allows users to filter events by keywords.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

Accessing the table from satellites page:

- **Device name**: Device name from the MNC system.
- **Alias**: Alias of antenna.

Accessing the table from antennas page:

- **Satellite name**: The name of the satellite to which this data set relates.

Common columns:

- **Azimuth**: Antenna azimuth pointing angle in degrees (floating point).
- **Elevation**: Antenna elevation pointing angle in degrees (floating point).
- **Polarization**: Antenna polarization pointing angle in degrees (floating point).
- **Target number**: Saved target number at antenna controllers.
- **Comment**: Text describing the purpose of this database entry.
- **Default**: Default position for selected antenna. Excluded from satellite page
- **Functions**: Action icons for managing the satellite position:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.14.3.1.1 Functionality

Create satellite position

- Click the + button at the top of the table to add a new satellite position.
- Input the required details.

Edit satellite position

- Click the *pencil icon* in the Functions column to modify satellite position details.
- Adjust the settings and save.

Delete satellite position

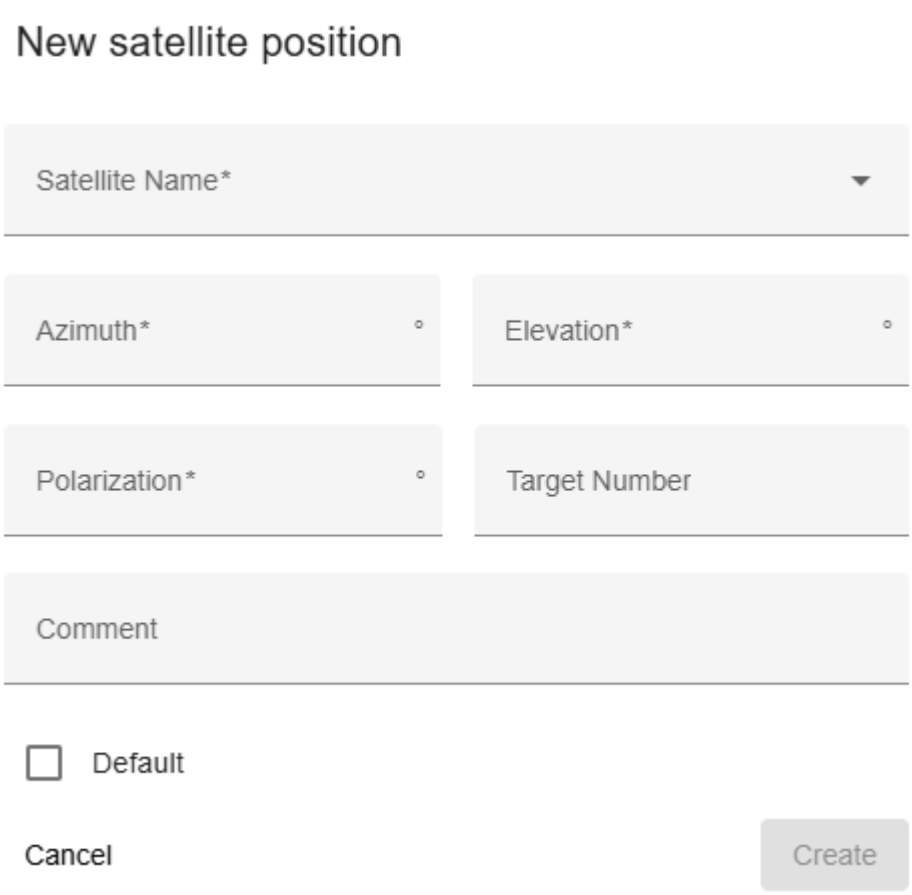
- Click the *trash icon* in the Functions column to delete an satellite position.
- Confirm the action in the pop-up dialog to delete the satellite position.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.14.3.1.2 Dialogs

Add/edit satellite position dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit satellite position in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Satellite name**: Select an satellite name from drop-down to which the data set should refer.
  - **Filename**: The name of the data file containing the position data of the satellite.
  - **Comment**: Free text describing the purpose of this dataset.
  - **Default**: Set position as default.

    - **Functions**: Action icons for managing the track:
        - **Edit**: Pencil icon to modify/edit.
        - **Delete**: Trash can icon to delete.

- **Actions**:

    - **Create/Save**:
        - For new position, this creates the satellite position with the provided details.
        - For existing position, this saves modifications.
        - If an error occurs in the input fields, the button is deactivated.
    - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an satellite position from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected satellite position.
- **Actions**:
    - **Yes**: Deletes the satellite position permanently.
    - **Cancel**: Cancels the deletion action.

2.14.3.2 Tracks table

Especially for fast moving satellites or satellites in a transition phase it may be necessary to move the antenna with a pre-calculate list of satellite postions. These list is called a track. Files with tracks are usually created by satellite operators. These files have one line per step with: timestand, azimuth, elevation and polarization.

Top

- Left-side title of table.
- Plus (+) button to create new track.
- Icon button to expand or collapse table

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon

near the column name.

Table columns

- **Satellite name**: The name of the satellite to which this data set relates.
- **Filename**: Saved name of the data file containing the position data of the satellite.
- **Comment**: Text describing the purpose of this database entry.
- **Default**: Default track for selected antenna.
- **Functions**: Action icons for managing the track:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.14.3.2.1 Functionality

Create track

- Click the + button at the top of the table to add a new track.
- Input the required details.

Edit track

- Click the *pencil icon* in the Functions column to modify track details.
- Adjust the settings and save.

Delete track

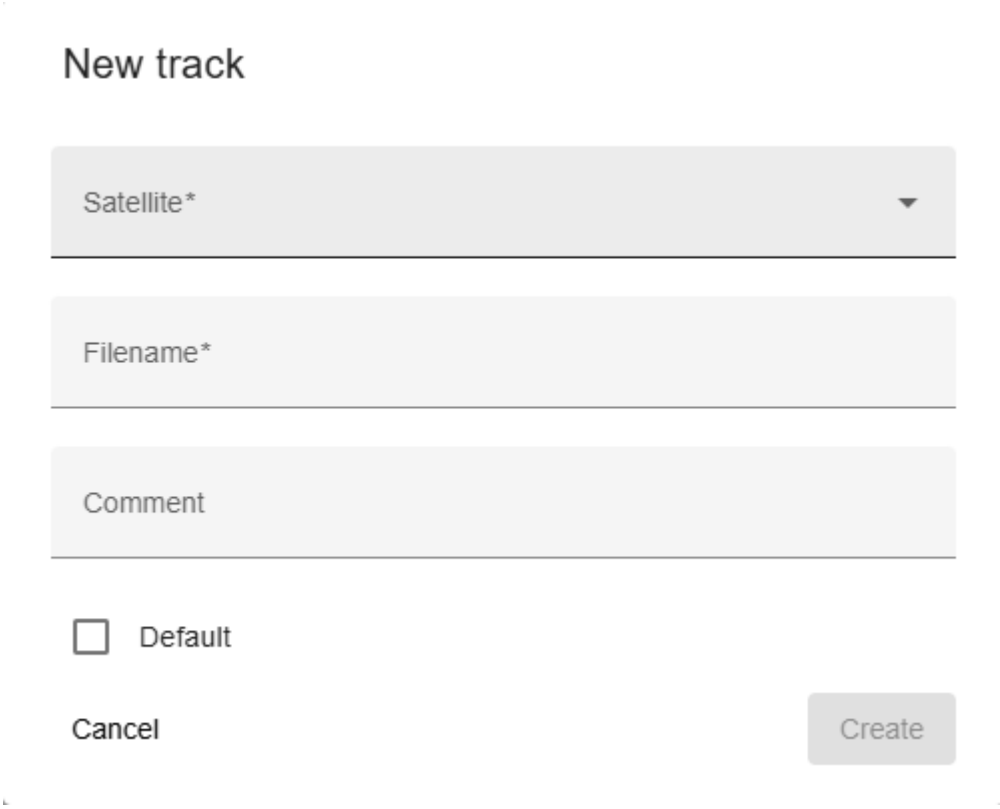
- Click the *trash icon* in the Functions column to delete an track.
- Confirm the action in the pop-up dialog to delete the track.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.14.3.2.2 Dialogs

Add/edit track dialog



- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit track in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Satellite name**: Select an satellite name from drop-down to which the data set should refer.
  - **Filename**: The name of the data file containing the position data of the satellite.
  - **Target number**: A target number to be set at some antenna controllers.
  - **Comment**: Free text describing the purpose of this dataset.
  - **Default**: Set track as default.
- **Actions**:
  - **Create/Save**:
    - For new track, this creates the track with the provided details.
    - For existing track, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an track from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected track.
- **Actions**:
  - **Yes**: Deletes the track permanently.

- **Cancel**: Cancels the deletion action.

2.14.3.3 Imports table

This tables contains the target list read from an ACU device.

Top

- Left-side title of table.
- Icon button to expand or collapse table

Search bar

- Located at the top of the table.
- Allows users to filter events by keywords.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Satellite name**: The name of the satellite to which this data set relates.
- **Azimuth**: Antenna azimuth pointing angle in degrees (floating point).
- **Elevation**: Antenna elevation pointing angle in degrees (floating point).
- **Polarization**: Antenna polarization pointing angle in degrees (floating point).
- **Target number**: Saved target number at antenna controllers.
- **Functions**: Action icons for managing the ACU-Target:
  - **Import**: Open a dialog to perform action.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and

navigate between pages.

2.14.3.3.1 Functionality

Import satellite position

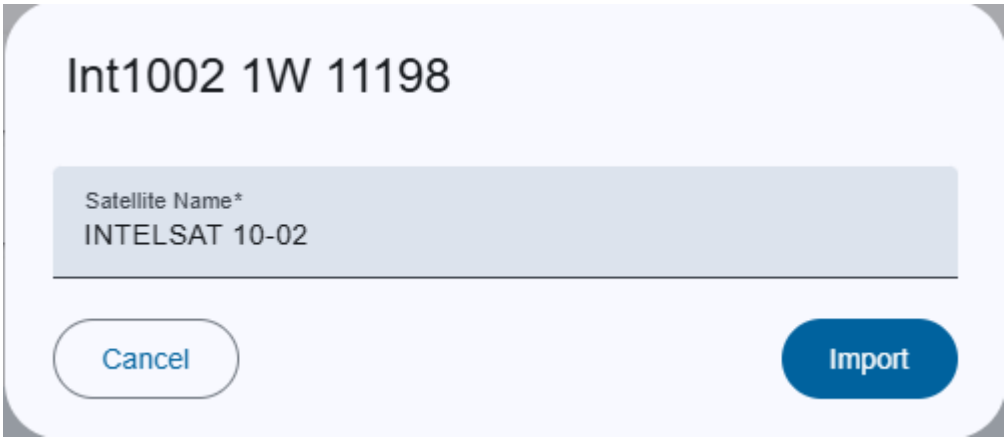
- Click the icon opens a dialog to import values.

Pagination

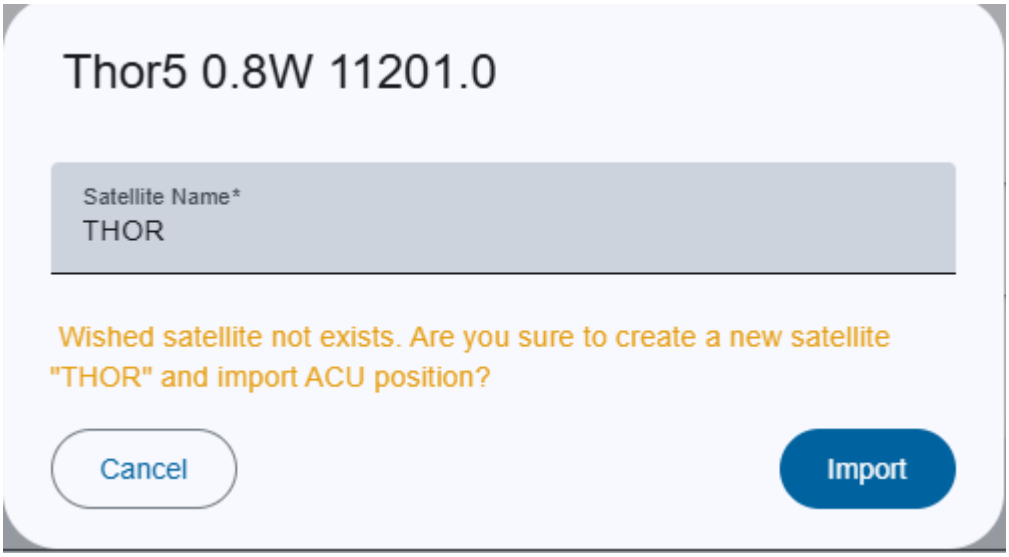
- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.14.3.3.2 Dialogs

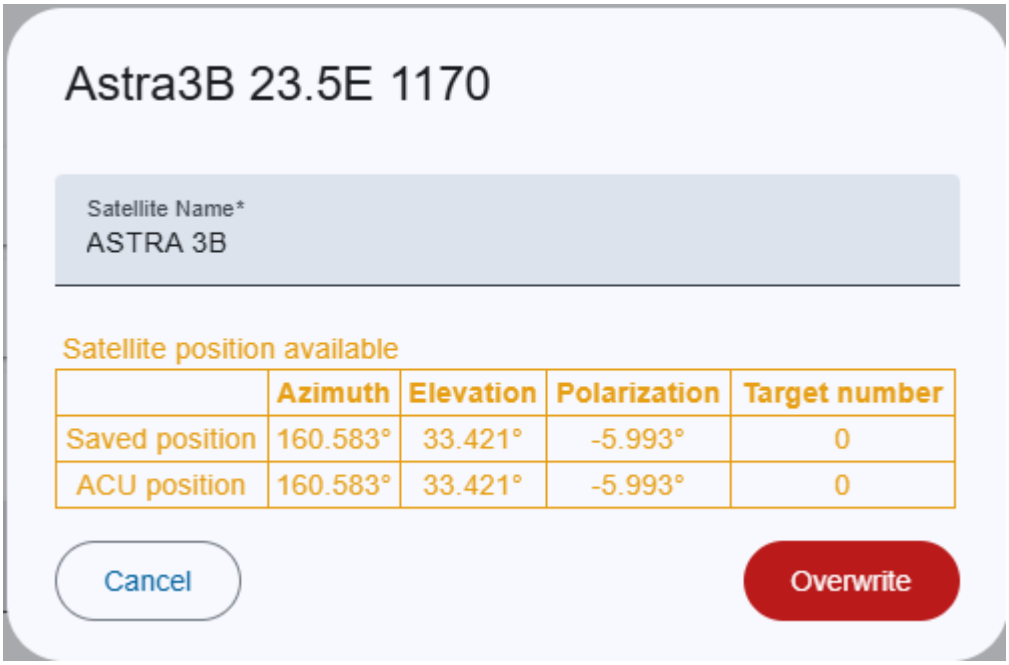
Import satellite position



- **Trigger**:
  - when you click on the icon to import values
  - The dialog title clearly indicates the name of "Satellite name" saved on ACU Target list
- **Fields**:
  - **Satellite name**: Select an satellite name from drop-down to which the data set should refer.
  - **Warnings**:
    - If the specified satellite is not saved



- If the satellite position is exists, the values of both are displayed to show the difference.



- **Actions**:
  - **Import/Overwrite**:
    - For new satellite or satellite position, this creates the satellite or satellite position with ACU-Target values.
    - For existing position, this overwrites with ACU-Target values.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

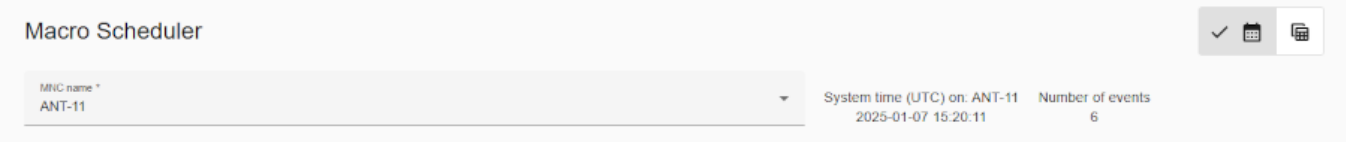
2.15 The Macro Scheduler

The Macro scheduler included in the sat-nms M&C software lets you execute macros at planned times. You access the macro scheduler from the main window by clicking to the toolbar icon which shows a alarm icon.

The Macro scheduler supports events which are executed once at a given time as well as repeated events on a daily, weekly, monthly or yearly base. Repeated events are executed in the planned was up to a given end date. Monthly repeated events are executed every month at the programmed day of month. If you program a monthly event for 29.-31. of a month, it will be executed at the last day of a month which is shorter.

The Macro scheduler page shows a list (in calender- or table-view) of planned events and provides controls to add, edit or delete events. Like with the macro/event management window, you may either select the recorded/stored macro you want to be played at the event's time or enter the commands manually.

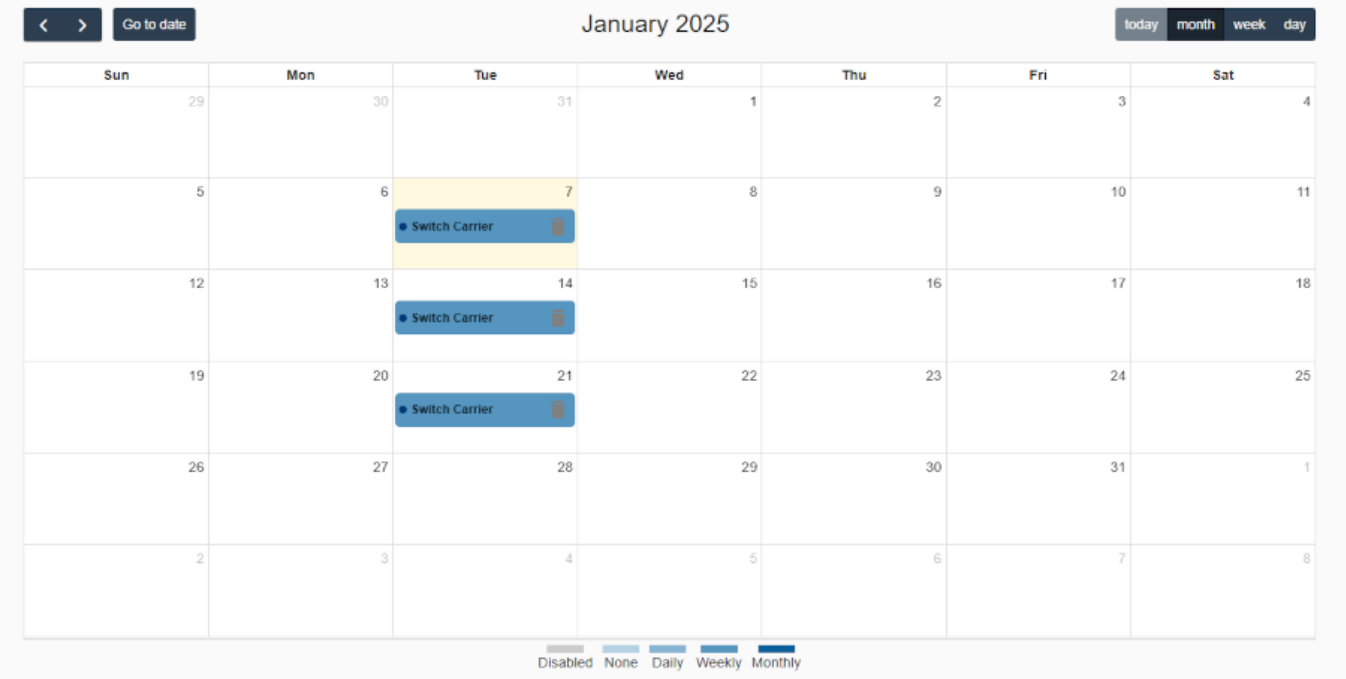
2.15.1 Scheduler



1. **Title**: Title of scheduler page.
2. **View options**: At the top right of the page are view options.
   - Calendar view (default)
   - Table view
3. **Select an MNC**: Below the heading and the view option, you must select an MNC from the drop-down list.
4. **Current system time**: After selecting the MNC near the drop-down list, the current system time in UTC is displayed.
5. **Total events**: Total number of events of the selected MNC is displayed.

2.15.2 Calender view

The Calendar View provides an interactive interface to visualize, create, manage, and track events based on different time frames (day, week, month). Users can navigate between dates, create new events, edit existing ones, reschedule an event by drag and drop, and distinguish events using a color-coded legend.



Navigation bar (top)

- **Left and right Arrows**: Use these arrows to navigate to the previous or next time-frame (month, week, or day, depending on the selected view).
- **Go to date button**: Click to open a dialog where you can select a specific year and month to navigate directly.

Current date

- In the middle, there is a heading displaying the current month and year. If you select a view other than the month, it will show the date range for the week or, for the day view, the specific month, day, and year.

View selection buttons

- Located in the top-right corner:
    - **Today**: If the current date is already displayed, the button is disabled. Otherwise, clicking the button takes you directly current date.
    - **Month**: Displays the calendar in a monthly view (default).
    - **Week**: Switches the calendar to a weekly view.
    - **Day**: Displays the calendar in a daily view.

Calender

- In the middle is the calendar view, displaying the selected view. Clicking on an event allows you to edit it, and clicking on the delete icon lets you delete the event. If you click on an empty date, you can create a new event. You can also reschedule an event by dragging and dropping it to a different date. A pop-up will appear to confirm the changes.
- Once an event is scheduled, the calendar will display it only on the set date. If the event

is set to repeat weekly, it will appear every week until it expires, and similarly for yearly or monthly or daily recurring events.

Color-coded legend (bottom)

- Clarification of the calendar colors, explaining what each color represents.

2.15.2.1 Features

Create event

- Click on an empty date to open the event creation dialog.
- Specify event details, including title, start date, end date, and recurrence type.

Edit event

- Click on an event to modify its details.
- Adjust the event date, recurrence, or other settings.

Delete event

- Use the trash icon within an event to delete it.
- Confirm the action in the pop-up dialog to delete the event.

Drag and drop rescheduling

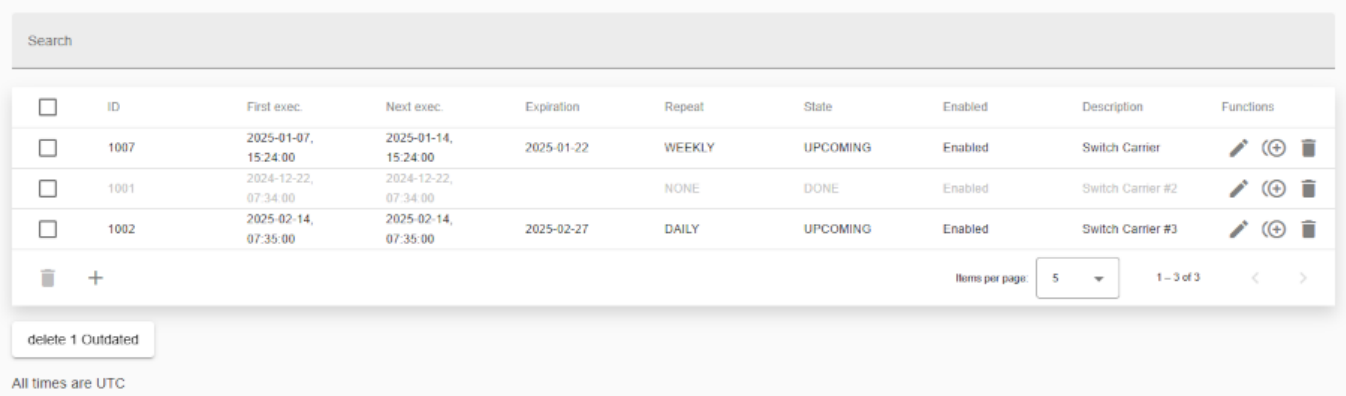
- Drag an event from one date to another to reschedule it.
- A confirmation dialog will appear to validate the changes.

Time frame navigation

- Navigate seamlessly using the arrows or the *Go to Date* button to jump to specific months, weeks, or days.

2.15.3 Table view

The Scheduler Table View provides a detailed interface to manage and monitor scheduled events. It allows users to view, edit, delete, and create events efficiently. All times displayed are in UTC.



Search bar

- Located at the top of the table.
- Allows users to filter events by keywords, such as ID, description, repeat type, etc.

Header row

- You can sort rows in ascending or descending order by clicking on the column header (e.g., ID, First Exec., Next Exec., etc.).
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
  - **Location**: The checkbox column is located at the far left of the table.
  - **Purpose**: Allows users to select one or multiple events for delete event.
  - **Functionality**:
    - **Single Selection**: Click on a single checkbox to select an individual event.
    - **Multiple Selection**: Click multiple checkboxes to select multiple events at once.
    - **Select All**: The checkbox in the header row allows you to select or deselect all events on all pages.
    - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **ID**: Unique identifier for each scheduled event.
- **First exec.**: The date and time when the event is scheduled to execute for the first time.
- **Next exec**.: The next scheduled execution date and time for the event.
- **Expiration**: The date when the event is set to expire and stop repeating.
- **Repeat**: Indicates the recurrence type of the event:
  - **NONE**: The event does not repeat.
  - **DAILY**: The event repeats every day until expiration.
  - **WEEKLY**: The event repeats weekly until expiration.
  - **YEARLY**: The event repeats yearly until expiration.
- **State**: Displays the current state of the event:
  - **UPCOMING**: The event is scheduled for a future execution.
  - **DONE**: The event has been executed.
- **Enabled**: Shows whether the event is active or disabled.
- **Description**: A brief description of the event.
- **Functions**: Action icons for managing the event:
  - **Edit**: Pencil icon to modify the event.
  - **Delete**: Trash can icon to remove the event.
  - **Duplicate**: Circular arrow icon to duplicate the same event.

Bottom toolbar

- **Delete selected events**: A button to delete selected events/rows from checkbox

column.
- **Create event**: + button is used to create new event.
- **Delete outdated**: A button to delete outdated events from the list.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.
- **UTC notice**: A reminder that all times displayed are in Coordinated Universal Time (UTC).

2.15.3.1 Features

Create event

- Click the + button at the bottom of the table to add a new event.
- Input the required details, such as execution time, expiration, recurrence type, etc..

Edit event

- Click the *pencil icon* in the Functions column to modify event details.
- Adjust the settings and save.

Duplicate event

- Click the *circular arrow* icon to duplicate an event.
- A dialog will appear with same settings (you can change some settings too).
- Click on save to preform action

Delete event

- Click the *trash icon* in the Functions column to delete an event.
- Confirm the action in the pop-up dialog to delete the event.

Delete outdated events

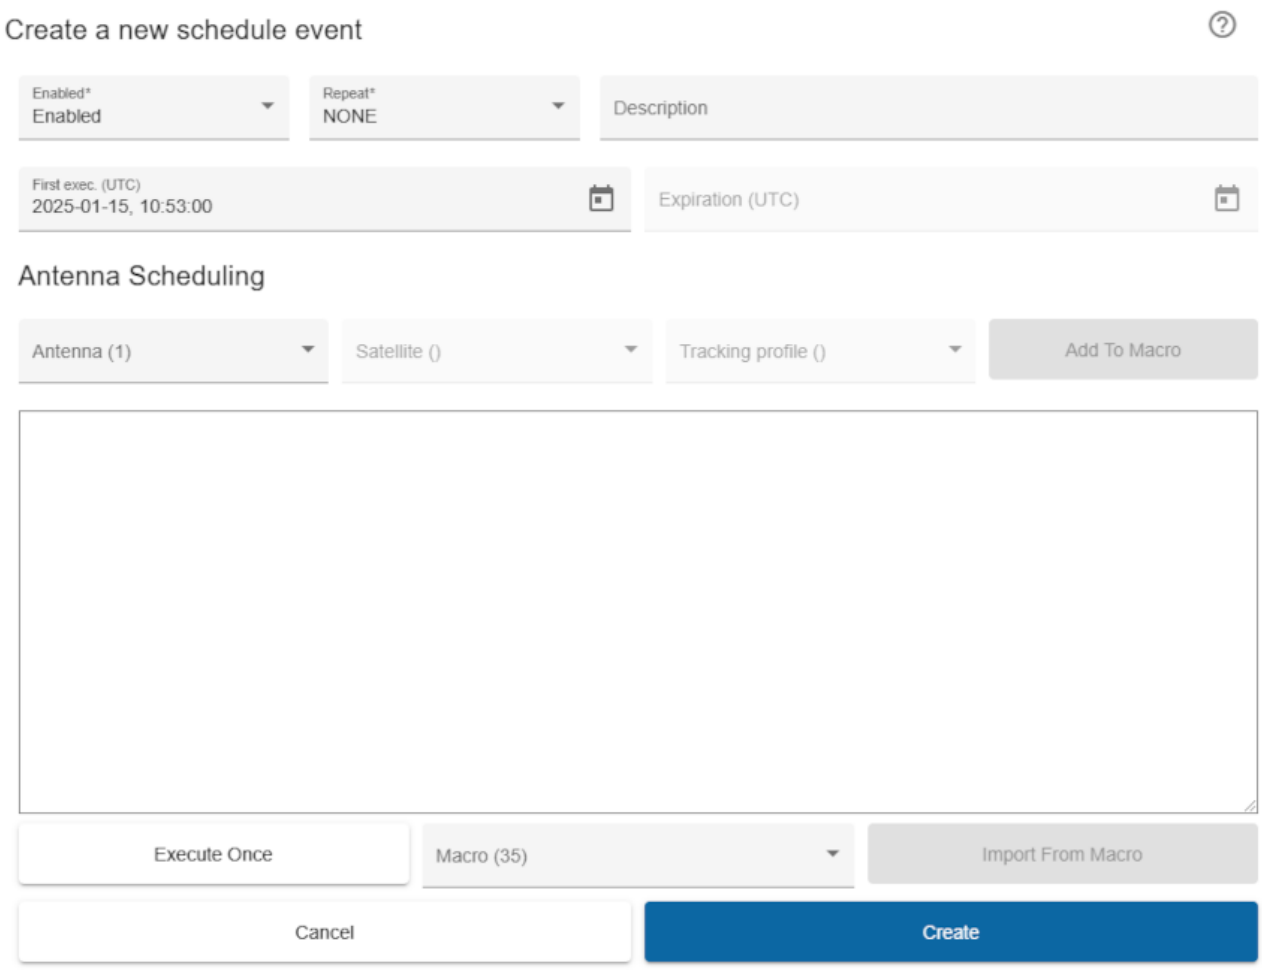
- Use the *Delete Outdated* button to remove all events that are no longer relevant or expired.
- Number shows that how much outdated events are there.
- A confirmation dialog will appear to with outdated event(s) details to perform action.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.15.4 Unified dialogs

Schedule-event dialog



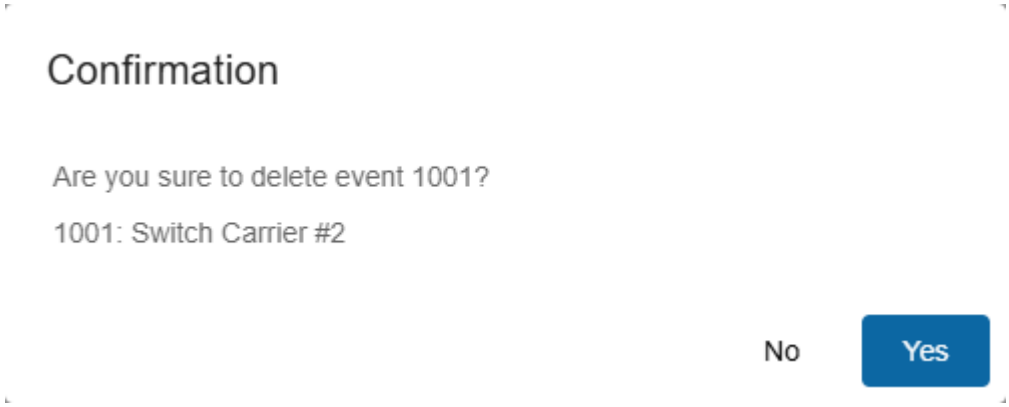
- **Trigger**:
  - when you click on an empty date in the Calendar View or the "+" button in the Table View (to create a new event) or
  - an existing event (to edit) in either the Calendar View on click on an event or in the Table View on *pencil icon* (to edit) or *circular arrow* (to duplicate) in the Functions column
  - The dialog title clearly indicates whether you are creating a new event, editing or duplicating an existing one, ensuring clarity in the action being performed.
  - There is a help button on the right-hand side that leads directly to the scheduler documentation.
- **Fields**:
  - **Enabled**: If enabled, the event is enabled. An enabled event will execute its macro at due time, a disabled event will skip this
  - **Repeat**: The repeat mode for the event. This may be one of:
    - **NONE**: The event is executed once at the date and time specified in "first execution".

        - **DAILY**: The event is executed first at the date and time specified in "first execution", then at all following days at the same time but not beyond the day given in "last execution" below.
        - **WEEKLY**: The event is executed first at the date and time specified in "first execution", then every seven days at the same time but not beyond the day given in "last execution" below.
        - **MONTHLY**: The event is executed first at the date and time specified in "first execution", then every month at the same day of month and time but not beyond the day given in "last execution" below. If you program a monthly event for 29.-31. of a month, it will be executed at the very last day of any month which is shorter.
    - **First exec. (UTC)**: The date and time of the first execution of the event (for repeated events) or simply the time of execution for an event executed only once. Click into the calender icon in field to open a pop up calendar widget which assists you entering the date. *NOTE: You have to enter time manually.*
    - **Description**: A brief description of the event.
    - **Expiration (UTC)**: The day of the last execution of the event.
    - **Antenna scheduling**: The Macro Scheduler provies a function to create easily a macro to start tracking at avert in antenna. The antenna scheduler function is only available for antennas which are managed by Antenna-Management devices. If there are no such devices configured in the M&C, the fields assigned to the antenna scheduler function appear disabled.
        - **Antenna**: Select an antenna from drop-down.
        - **Satellite**: Select an satellite from drop-down.
        - **Tracking profile**: Select an tracking profile from drop-down.
        - **Add to macro**: Replaces the macro text with a fragment which sets up the antenna for the selected satellite and tracking mode and starts tracking on it. Additional commands / parameter settings may be added to the macro (below this button in text field) before the schedule event gets saved.
        - **Macro text**: Brief description of an macro to be saved. It is also editable.
    - **Macro**: Select an recorder macro from drop-down list.

- **Actions**:

    - **Execute Once**: To execute the macro once. Useful for testing the macro.
    - **Import From Macro**: It imports the selected macro and displays the details in the free area above it.
    - **Create/Save**:
        - For new events, this creates the event with the provided details.
        - For existing events, this saves any modifications.
    - **Cancel**: Closes the dialog without saving.

On delete event confirmation dialog

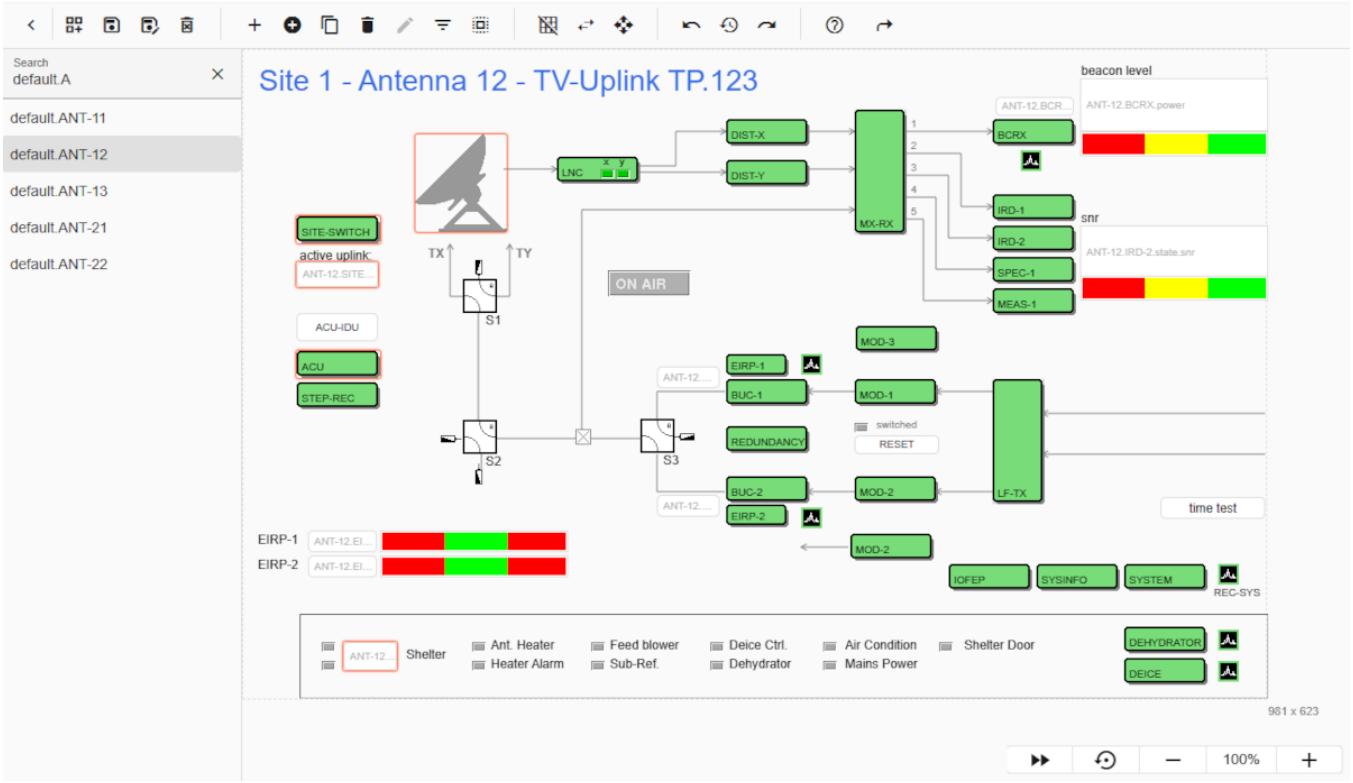


- **Trigger**: Opens when you click the trash icon for an event in either view or click delete outdated in table view.
- **Content**: Asks the user to confirm whether they want to delete the selected/outdated event(s).
- **Actions**:
  - **Yes**: Deletes the event(s) permanently.
  - **Cancel**: Cancels the deletion action.

2.16 Screen editor

The Screen editor is used to layout or configure the M&C windows called user screens used in the M&C user interface.

The Screen Editor works like a simple drawing program. Each M&C user screen contains a number of objects (elements) which may be placed, sized and edited using the screen Editor.



Toolbar

The toolbar options and their functions are described below. If you move the mouse pointer over the icon, the tooltip is displayed with a brief description.

- **Toggle screen list**: Clicking on arrow to left (<, >) toggle the screen list.
- **Create new screen**: Opens a create new screen dialog.
- **Save screen**: Save the modifications.
- **Save screen as**: Save the selected screen under other name.
- **Delete screen**: Delete the selected screen.
- **Add element**: Opens a panel on the right side to add an element.
- **Insert screen**: This option is used to insert an other user screen elements to selected screen.
- **Duplicate element(s)**: Duplicates the selected element(s) with there properties. The new element(s) appears on top of existing one.
- **Delete element**: Deletes the selected element(s). You can also use backspace or delete key to perform this action.
- **Edit element**: Opens a element properties panel on right side of selected element. You can also use double click to edit element.

- **Select element type**: This option is used to select all elements according to their type. If you click on this option, an input field would be displayed. When you start typing, the element list is filtered and you can select an option. All elements with the type you have selected from the option will be selected.
- **Select all elements**: Select all elements. You can also use `ctrl + a` .
- **Grid positioning**: Elements are placed along a invisible 3 x 3 pixel grid if they are moved while this options in on.
- **Push element to background**: Moves the selected element to the back so it does not cover any other element.
- **Alignment**: Aligning a group of elements. The first selected element is the parent element, i.e. the properties are transferred from the parent element to the child elements.

  - **Same width**: It is used to have the same width as the parent element.
  - **Same height**: It is used to have the same height as the parent element.
  - **Same size**: It is used to have the same width and height as the parent element.
  - **Align left**: Align the elements to the left of parent element.
  - **Align right**: Align the elements to the right of parent element.
  - **Align top**: Align the elements to the top of parent element.
  - **Align bottom**: Align the elements to the bottom of parent element.
- **Undo**: To go to previous change. Can also be used with `ctrl + z` .
- **History**: All changes made by a user are saved in the history. If you click on the clock

symbol, a list of all changes is displayed with the number and date-time (1: yyy-mm-dd HH:mm:ss). If you click on an option, you will be taken to this specific change.

- **Redo**: To go to forward change. Can also be used with `ctrl + y` .
- **Help**: Bring you to help page of screen-editor.
- **Shortcuts**: List of all key combinations.

Screen List

List of all saved screens on the server. Select the name of the screen you wish to edit.

Editing area

After selecting the screen, the screen elements are loaded into the editing area on the right-hand side like in image above. If you look closely, some elements have a *light red* border, which means they are selected. You can simply start dragging, resizing, etc. to perform functions. The functionality is described next in functionality section.

- There is a small toolbar on the bottom right-hand side of the editor. The functions are there:
  - **Jump to user-screen**: You can go direct jump to the user-screen.
  - **Reset position**: If you click on this button, the position of the screen editor is reset.
  - **Zoom out**
  - **Current zoom**: Displays the current zoom of the screen monitor. Clicking on the number restores the standard zoom (100%).
  - **Zoom in**

2.16.1 Functionality

Double click: Double click on an element to edit the element properties.

Resize element: Once you have selected the element, you can change the size of the element in any direction from the corner of the element. If you move the mouse over it, the mouse pointer changes from the standard pointer to the corresponding direction pointer.

Select multiple elements: Just hold down hte `ctrl` key and click on that element you want to select.

Reposition element(s): Once you have selected an element(s), you can drag it to the desired location and drop it there.

Edit element properties: You can edit the element properties in the *Element properties* panel. This is displayed on right hand side of editor when you double-click on the element or click *pencil icon* to edit the selected element in the toolbar.**Duplicate element(s)**: Duplicates the selected element(s) with there properties. The new element(s) appears on top of existing one. **Delete element**: Deletes the selected element(s). You can also use backspace or delete key to perform this action. **Zooming**:

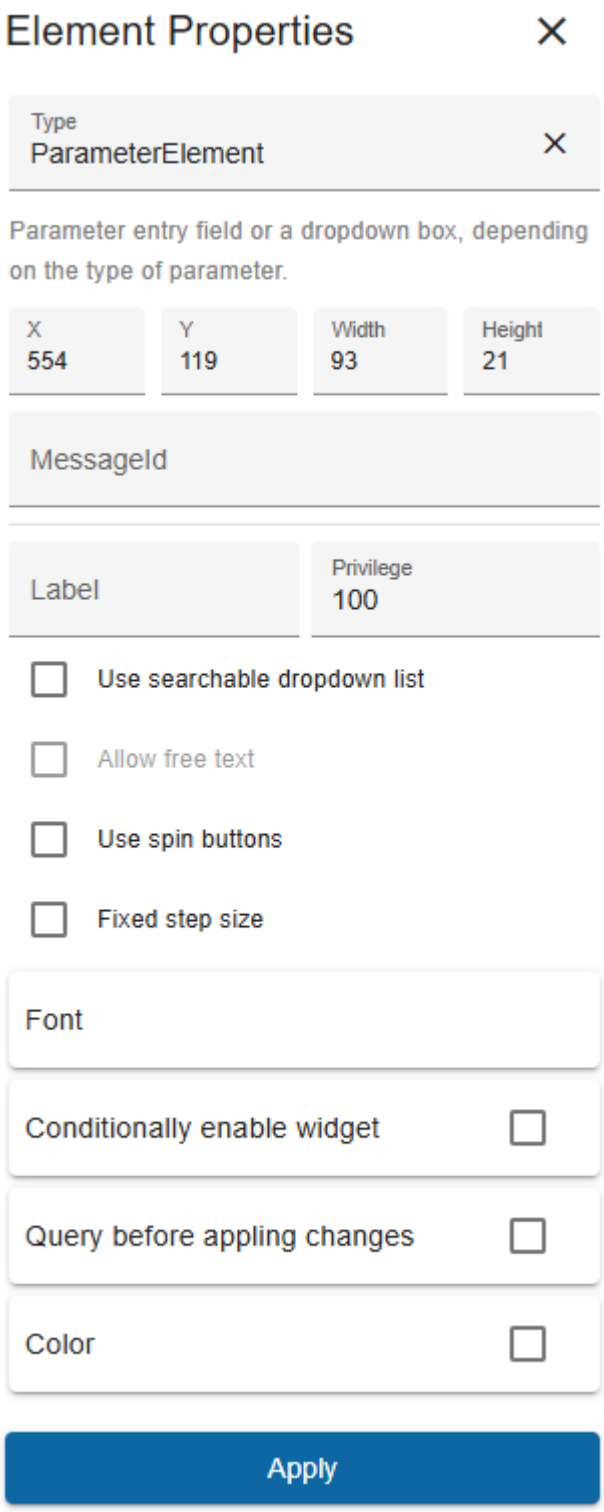
- **Key combinations**
  - **Zoom in**: By hold down `ctrl` key and pressing `+` key.
  - **Zoom out**: By hold down `ctrl` key and pressing `-` key.
  - **Default zoom (100%)**: By hold down `ctrl` key and pressing `0` key.
- **Mouse and key combination**: Simply hold down `ctrl` key and scroll with `mouse wheel`

Move screen: By hold down `space` key and hold down `mouse click` and then move the mouse, the screen will move in the direction in which the mouse is moving.

Horizontal scroll: By hold down `shift` key and scroll with `mouse wheel`

2.16.2 Element properties

The window for the properties of a screen element is used to define the properties of a display element within the screen editor. The screen editor uses the same window with the element properties for all elements. If you click on another element in the editor window, the available properties of this element are loaded into the properties window, which may contain different fields/information depending on the type of screen element. The element properties for the general *parameter element* are shown below as an example:



Each element has the properties type, x, y, width and height.

1. **X**: X location of the element in the user screen.
2. **Y**: Y location of the element in the user screen.
3. **Width**: Width of the element's bounding box.

4. **Height**: Height of the element's bounding box.
5. **Type**: The type of the element. When you add a new element, ParameterElement is the default value. When editing an element, the type of element will be selected element type.

NOTE: All sections like *Font or Color* are expandable sections. Just click on that section to expand or collapse.

2.16.2.1 Display element types and their properties

The table below shows the types of display elements the screen editor supports. A detailed description of the individual element types is given on the following pages.

Type	Description
Arrow element	Draws a horizontal/vertical line or arrow.
AzEl element	A chart showing the tracking history of an antenna controller as a point cloud in an elevation over azimuth coordinate system.
Button element	Defines a button which launches another screen, e.g. for detail views.
Chart element	A chart element, displaying a numeric parameter as an y/t diagram that automatically advances with 1 pixel / second.
Device icon element	Places an icon into the screen which represents a device. This icon will display the device's operating/fault state by it's color / shape.
Display element	A parameter display field in which the parameter cannot be edited.
Frame element	Draws a sunken 3D frame, may be used to group parameters.
Gauge element	A gauge element, displaying a numeric parameter as a horizontal bar.
Icon element	Places an icon (GIF or JPG image) into the screen. Optionally the icon can be programmed to change with a parameter value.
Latching button element	A button which displays/controls a 2-state parameter using it's pressed state.
Parameter button element	A button which sends a certain parameter value when pressed.

Type	Description
Parameter element	A parameter entry field.
Radio button element	A parameter entry field specially for **Choice** parameters.
Rect element	Draws a rectangle.
Spectrum element	The spectrum display element integrates the spectrum display of a spectrum analyzer device in a user screen.
Switch element	Like the device icon. but additionally displays the actual position of a switch (Meant to be used for block diagrams showing the true signal path).
Target list element	The ODM Target List element shows the list of targets of a SatService-ACU-ODM antenna controller device. It permits to recall, save or delete target definitions of this type of antenna controller. It is specialized to this antenna controller, does not support other types.
Text element	Displays a line of text.
Thumbnail icon element	A screen element to show thumbnail images from the video processed by an encoder / decoder / gateway device which supports this feature.
XY chart element	This element shows the relation of two numeric variables in an X/Y diagram, featuring a trace which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.

2.16.2.1.1 Button element

The button (frame) display element creates a button which launches another user interface screen if pressed. The screen to be launched may be another user defined screen or a predefined one.

The attributes listed below may be configured to customize a display element of this type:

- **Label**: The label text is drawn on the button.
- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.

- **Use icon instead of label**: Check this checkbox in order to make the button show an icon instead of a label text.
- **Icon**: Provides a list of all available icons / images on the sat-nms server.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Button action**: with this field you select the function of the button. The available functions are listed below. The meaning of the parameters right beside the function selector changes with the function selected.
  - **BROWSER-VIEW**: Launches the platform's standard web browser and shows the given URL. URL must be entered.
  - **CHILD-SCREEN**: Launches a new screen in a separate window. Screen name must be entered.
  - **FREC-VIEW**: Launches a graphical presentation screen for data recorded with a File-Recorder logical device. MNC.device name must be provided (e.g. ANT-11.REC-SYS).
  - **LOAD-PRESET**: Launches a dialog to select and apply a preset to a given device. MNC.device name must be provided (e.g. ANT-11.REC-SYS). You can also set driver and search pattern. Search pattern field with this value. Only presets containing the pattern string (character case doesn't matter) will appear in the list.
  - **REPLACE-SCREEN**: Replaces the actual screen by another one, re-uses the same window.
  - **SPECTR-VIEW**: Launches the device window of a spectrum analyzer and optionally sets an arbitrary number of parameters. MNC.device name must be provided (e.g. ANT-11.REC-SYS). *An optional macro list*: This may contain zero or more parameter ID - value pairs. These settings may be used to preset the spectrum analyzer certain settings but also to control switches or other devices in the signal path. Example: S03=B, SA1.center=12345.666 If the operator clicks to this button, the switch S03 is commanded to position B, the spectrum analyzer SA1 is set for a center frequency of 12345.666 MHz and the spectrum analyzer window gets opened.
  - **TRACK-VIEW**: Launches a tracking report window for the Antenna-Tracking logical device. The tracking report window shows azimuth or elevation together with the beacon level over the recent 48 hours. MNC name and ACU driver must be provided. Typically this is the "state.mode4" Parameter of an Antenna-Tracking or a SatService-ACU-ODM device.
  - **TREE-NAVIGATE**: This button used to navigate to tree devices as user screen. Tree path must be MNC.Subsystem (e.g. ANT-11.GATES)

- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.

    - **Enable ID**: This field defines the ID for the enabling parameter.
    - **Enable value**: The value belonging to the parameter above. The actual value of the parameter

- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.

    - **Color ID**: The message ID of the parameter which controls the background color of this element.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Value**: The parameter value of the actually selected table entry.
    - **Bold**: Draws the text bold if the parameter value matches.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
    - **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.2 Parameter element

The *Parameter* display element is the common component to display and edit most types of M&C parameters. Depending on the data type of the parameter (the data type is detected automatically) the parameter elements appears as textual / numeric entry field, choice box or as display field for read only parameters. In the screen editor, the parameter element is shown as a sunken rectangle.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.

- **Label**: The label text is drawn above the element.

- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to

higher privilege levels, limiting the group of operators permitted to change the parameter.

- **Use searchable dropdown list**: Checking this mark changes the type of drop down list to be used with a choice parameter. Enumerated values normally are shown as a dropdown list which pops up if you click into the field and can be filtered if you start typing. You always have to select the value with the mouse click or keyboard arrows and then enter key. *If the widget is configured for a height of 40 pixels or more, it appears as a scrollable list rather than as a dropdown*. Checking *Use searchable dropdown lis* also enables the *Allow free text*.

- **Allow free text**: This is also a drop-down list as a searchable drop-down list. In addition, you do not have to select from the dropdown options, but can simply enter any text and save it with the Enter key.

- **Use spin buttons**: Checking this mark enables "spin buttons" for numeric entry fields. Clicking these small arrow symbols at the right edge of the entry field increases/decreases the value by a certain amount. clicking them with the right mouse button increases/decreases by a larger amount.Enabling spin buttons with automatic step size automatically enabled the "Fixed step size".

- **Fixed step size**: Checking this mark permits to set user defined increment values for the spin buttons. If not checked, the spin button increment is derived from the least significant digit shown in the field, the large (right mouse button) increment is ten time that.

    - **Small steps**: The spin button increment value to be applied with left mouse button clicks.
    - **Large steps**: The right mouse button spin button increment. The program assumes 10 times the small steps if the large steps field is left empty.

- **Font**: Font contains two options:

    - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
    - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.

- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.

    - **Enable ID**: This field defines the ID for the enabling parameter.
    - **Enable value**: The value belonging to the parameter above. The actual value of

the parameter

- **Query before applying changes**: Check this mark to make the element show a query before a parameter gets actually commanded.
    - **Query text**: The query text to be shown in the pop-up window. You may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern `$P` get replaced by the parameter name (message ID). Any occurrences of the pattern `$V` get replaced by the new value to set.
- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
    - **Color ID**: The message ID of the parameter which controls the background color of this element.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Value**: The parameter value of the actually selected table entry.
    - **Bold**: Draws the text bold if the parameter value matches.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
    - **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

NOTE

- The options "use spin buttons" (automatic step size) and "use editable drop down list" internally use the same use the same property of the screen element. Hence, these options are linked in way that if you enable one of these options, the other one is selected as well. This is done to maintain compatibility to older versions of the software. This linkage means no limitation, as a parameter element never can be a numeric entry field and a choice list at the same time.
- If you enlarge the height for a choice parameter widget to more than 40 pixels, the software uses a list widget with scroll bars rather than a drop down selection box.
- If you enlarge the height for a entry field to more than 50 pixels, the software uses a multi line entry field widget. Multi line entry fields are useful only for very few types of parameters, they are not recommended for general use.

2.16.2.1.3 Display element

The display element also known as read-only-parameter element is used to display M&C parameters as read-only. It looks much alike the parameter element, but never allows to

change the parameter it displays.

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label**: The label text is drawn above the element.
- **Draw frameless with transparent background**: Activate this option so that the element is drawn without an input field frame and with a transparent background. With this option, the read-only parameter element can be used as a label that changes its text with the value of a variable. Please note that you cannot use the *color (Variable background color)* option (described below) together with the frameless / transparent background option.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.
  - **Enable ID**: This field defines the ID for the enabling parameter.
  - **Enable value**: The value belonging to the parameter above. The actual value of the parameter
- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
  - **Color ID**: The message ID of the parameter which controls the background color of this element.
  - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
  - **Value**: The parameter value of the actually selected table entry.

- **Bold**: Draws the text bold if the parameter value matches.
- **Add**: To add a new value / color pair to the list, fill the value and color fields.
- **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
- **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.4 Radio button element

The radio buttons display element is a component for displaying and editing M&C parameters of the CHOICE type in the form of a row of radio buttons. Depending on the height of the element, the radio buttons are arranged in a row or in a column. In the screen editor, the parameter element is displayed as a simple rectangle.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label**: The label text is drawn above the element.
- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- **Draw frame**: Checking this checkbox makes the element show a rectangular frame around the radio buttons.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.
  - **Enable ID**: This field defines the ID for the enabling parameter.
  - **Enable value**: The value belonging to the parameter above. The actual value of

the parameter

- **Query before applying changes**: Check this mark to make the element show a query before a parameter gets actually commanded.
    - **Query text**: The query text to be shown in the pop-up window. You may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern `$P` get replaced by the parameter name (message ID). Any occurrences of the pattern `$V` get replaced by the new value to set.
- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
    - **Color ID**: The message ID of the parameter which controls the background color of this element.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Value**: The parameter value of the actually selected table entry.
    - **Bold**: Draws the text bold if the parameter value matches.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
    - **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.5 Text element

The text display element shows a label (a one line text string) with a selectable font / color.

The attributes listed below may be configured to customize a display element of this type:

- **Label**: The label text is drawn above the element.
- **Font**: Font contains two options:
    - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
    - **color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.

2.16.2.1.6 Frame element

The Frame display element draws a sunken 3D frame, which is intended to be used to group other elements. *Beside the position in the window there are no user configurable attributes to set.*

NOTE

- The 3D frame's inside area is transparent, it does not conceal the screen elements it encloses. In the screen editor, however the 3D frame grabs all mouse clicks, so you might not be able to mode the elements which are inside the frame. In this case move the 3D frame to the back by pressing *push element to background* while the frame element is selected. The other elements are now "on top" of the frame element and may be addressed by the mouse independently.

2.16.2.1.7 Rect element

The rect (rectangle) display element draws a rectangle with a selectable color.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Color**: The color to be used to draw the rectangle unless a variable line color is specified. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Filled rectangle**: If this checkbox is checked, a solid rectangle is drawn. The*raw bold* property in the color translation table has no effect when the rectangle is drawn solid.
- **Use variable line color**: Check this checkbox to let draw the rectangle with a color specified by the value of the variable specified by 'message ID'. Unless you check the mark 'use color translation table'
- **Use color translation table**: Checking this checkbox enables a color translation table which works much like the variable background color feature for entry elements. Depending on the actual value of the variable addressed by 'message ID', the element's line color and thickness is set using the translation table shown in the lower left corner of the dialog. If the actual value of the variable does not match any of the table entries or if no message ID is specified, the first color in the list is used to draw the element's background.
    - **Value**: The parameter value of the actually selected table entry.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Bold**: Specifies the line width of the currently selected table entry. If the checkmark is checked, the line is drawn 3 pixels wide, if the checkbox is not checked, the line width is 1 pixel.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.

- **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.8 Arrow element

The arrow display element draws a horizontal or a vertical line and optionally an arrowhead. The line's color is selectable. Strictly speaking the Line / Arrow element is a rectangle with only one or two sides drawn.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Color**: The color to be used to draw the line unless a*use variable line color*is specified. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Arrows and lines**: You can choose the arrow or line from options. Simply click the option.
- **Use variable line color**: Check this checkbox to let draw the line with a color specified by the value of the variable specified by 'message ID'. Unless you check the mark 'use color translation table'.
- **Use color translation table**: Checking this checkbox enables a color translation table which works much like the variable background color feature for entry elements. Depending on the actual value of the variable addressed by 'message ID', the element's line color and thickness is set using the translation table shown in the lower left corner of the dialog. If the actual value of the variable does not match any of the table entries or if no message ID is specified, the first color in the list is used to draw the element's background.
  - **Value**: The parameter value of the actually selected table entry.
  - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
  - **Bold**: Specifies the line width of the currently selected table entry. If the checkmark is checked, the line is drawn 3 pixels wide, if the checkbox is not checked, the line width is 1 pixel.
  - **Add**: To add a new value / color pair to the list, fill the value and color fields.
  - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
  - **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.9 Icon element

The icon display element shows an arbitrary GIF/JPEG picture. The image file must reside in the ./images directory on the M&C/NMS server.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Icon**: Selects the name of the image/ icon from dropdown list. Once you selected the icon preview will be displayed below the icon input field.

Using an icon to display a parameter

If you specify a message ID with the element properties of an Icon , the image displayed will change with the parameter value addressed by the message identifier.

You must supply one image file for each value the parameter may have. The parameter value must appear in the file name just in front of the gif/jpg suffix, enclosed in dots. All images used for one parameter should be of the same size. If the Icon element receives a parameter value it does not find an image file for, a black rectangle is displayed instead of an image.

Example: Let's assume you want to visualize a TX ON/OFF switch with an antenna symbol changing it's color with the position of the switch. Supply two images called "transmission.ON.gif" and "transmission.OFF.gif" which symbolize these states as you want. Notice that the ON/OFF keywords in the file names exactly reflect the possible values of this parameter and that the file names only differ in this point. Select one of image files for the icon element and enter the message Id of the TX-ON/OFF parameter into the appropriate field.

The mechanism used to select the image file to display mostly limits the usage of dynamically changing icons to CHOICE parameters. Merely numeric (integer) parameters with a very limited number of possible values come into question, too.

Using an icon to display a device summary fault

With device summary faults ("DEVICENAME.fault"), and subsystem faults ("SUBSYSTEM. ... .fault") the Icon element translates the fault state to "true" for FAULT and "false" for "OK.". This is because the sat-nms software provides the individual fault flags in a device driver as boolean values, the summary fault however is represented by a text which can be one of "OK.", "WARNING" and "Summary FAULT". Translating the OK/FAULT values lets you use the same image files for individual and summary fault states.

To display a device summary fault as an color changing icon, you have to provide three image files, for example:

MyIcon.false.gif for the "OK" state **MyIcon.WARNING.gif** for the "WARNING" state **MyIcon.true.gif** for the "FAULT" state

2.16.2.1.10 Device icon element

The device icon display element represents a device in the M&C user interface. It displays the status of the device by it's color/shape and gives access to the *device details panel* panel for this particular device by a mouse click.

The attributes listed below may be configured to customize a display element of this type:

- **Device name**: The name of the device this element stands for.
- **Icon**: Selects the device icon / image from dropdown list to display. Once you selected the icon preview will be displayed below the icon input field. The sat-nms software at least provides three predefined icons for this purpose:
  - : device-rectangle.gif
  - : device-square.gif
  - : device-minirect.gif
- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- **Show device name**: Check this checkbox to display the name of the device as a label in the icon. Unchecked can be useful if very small icons are used in which the label would not fit, or if a label is to be used that is different from the name of the device.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Signal if device actually is redundant**: Check this checkbox to apply a special coloring for devices which are in the redundant signal path of a redundancy switching facility.
  - **Redundancy signal ID**: The message ID of a parameter which gives the information if the device actually operates as the redundant one or if it is operational. For a 1:1 TWTA redundancy this could be the position parameter of the waveguide switch which selects the signal from the two TWTAs
  - **Redundancy signal value**: If the value of the parameter addressed by above message ID matches the value given in this field, the device icon is shown as "redundant" (depends in the icon set used, the factory icon sets use a blue background color for this).

Using customized images

You may supply your own images for the device icon display element. To do so, place seven images into the *./images* directory named "xxxxx.gif", "xxxxx-F.gif" (fault), "xxxxx-C.gif" (communication fault), "xxxxx-S.gif (fault suppressed)", "xxxxx-R.gif" (redundant), "xxxxx-O.gif" (out of service) and "xxxxx-M.gif" (maintenance). You should consider the following:

- All images should be of the same size.
- The software places the device name at the lower left corner of the image using the selected font and color. All four images should use appropriate colors in this area to keep the device name visible.
- Beside GIF-images the software also accepts PNG images (file extension .png) and JPG images (file extension .jpg). All images of a set must be of the same type (GIF/PNG/JPG).

Using a customized 'transmitting' emblem

For devices which provide the 'info.signal.on' parameter to report that the device is actually transmitting or receiving, the device icon shows an emblem at it's upper right corner. The software uses the 'signal-on-emblem.png' image as a default for this.

You may define individual emblems for each image set by placing a "xxxxx-X.gif" (or .png/.jpg) image in the ./images folder with xxxxx being the base name of the device icon. The software will use this file for the transmitting emblem of this particular icon set. The file extension of the emblem must match the extension of the base icon image.

2.16.2.1.11 Parameter button element

The Parameter Button display element is a button which sends a parameter value if pressed. A frequently used application for the parameter button is a RF-OFF button which sends a "tx.on=OFF" to a certain device. Beside this, a parameter button also may be programmed to play a parameter setting macro.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label**: The label text is drawn above the element.
- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- **Start macro**: Selects if the button shall start a macro (checked) or send a certain parameter (unchecked).
- **Use icon instead of label**: Check this checkbox in order to make the button show an icon instead of a label text.
    - **Icon**: Provides a list of all available icons / images on the sat-nms server.
- **Specify values to send**: Checking this checkbox let you define the parameter value to be sent with a button click. Without this option the button sends the label text as a parameter value:

    - **Parameter value**: The value to be sent when the button is clicked.

- **Font**: Font contains two options:

    - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
    - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.

- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.

    - **Enable ID**: This field defines the ID for the enabling parameter.
    - **Enable value**: The value belonging to the parameter above. The actual value of the parameter

- **Query before applying changes**: Check this mark to make the element show a query before a parameter gets actually commanded.

    - **Query text**: The query text to be shown in the pop-up window. You may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern `$P` get replaced by the parameter name (message ID). Any occurrences of the pattern `$V` get replaced by the new value to set.

- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.

    - **Color ID**: The message ID of the parameter which controls the background color of this element.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Value**: The parameter value of the actually selected table entry.
    - **Bold**: Draws the text bold if the parameter value matches.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
    - **Delete**: To delete a value / color pair from the list, first select the table entry then

click delete.

2.16.2.1.12 Latching button element

The Latching Button display element works much like the Parameter Button element described in the previous chapter, but specialized to show and control an enumeration parameter which knows exactly two states (e.g. on/off or true/false).

When the operator changes the state of the button by clicking it once, the latching button sends the 'other' parameter value to the device. On the other hand, if some other instance in the system changes the parameter state, the latching button recognizes this and changes the up/down state of the button accordingly.

Like the parameter button, the latching button may be labeled with text or an image. To reflect the actual state, the latching button always is configured with two text string or two image names which are shown according to the actual parameter value.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label up**: This label text is drawn on the button in "up" state.
- **Label down**: This label text is drawn on the button in "down" state..
- **Value up**: The value to be sent when the button is clicked an changes to "up" state.
- **Value down**: The value to be sent when the button is clicked an changes to "down" state.
- **Privilege level**: The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- **Use icon instead of label**: Check this checkbox in order to make the button show an icon instead of a label text.
    - **Icon up**: The name of the icon to be shown in "up" state of the button. The field provides a list of all available icons / images on the sat-nms server.
    - **Icon down**: he name of the icon to be shown in "down" state of the button. The field provides a list of all available icons / images on the sat-nms server.
- **Font**: Font contains two options:
    - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except

the smallest one. In the latter case the label is drawn using this small font size, too.
    - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.

- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.

    - **Enable ID**: This field defines the ID for the enabling parameter.
    - **Enable value**: The value belonging to the parameter above. The actual value of the parameter

- **Query before applying changes**: Check this mark to make the element show a query before a parameter gets actually commanded.

    - **Query text**: The query text to be shown in the pop-up window. You may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern `$P` get replaced by the parameter name (message ID). Any occurrences of the pattern `$V` get replaced by the new value to set.

- **Color**: Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by *color id*, the element's background is set using the translation table. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.

    - **Color ID**: The message ID of the parameter which controls the background color of this element.
    - **Color**: The color specification of the actually selected table entry. Clicking to this opens a color chooser dialog which lets you select/compose the the color to your needs.
    - **Value**: The parameter value of the actually selected table entry.
    - **Bold**: Draws the text bold if the parameter value matches.
    - **Add**: To add a new value / color pair to the list, fill the value and color fields.
    - **Set**: To change the color assigned to a given parameter value, first select the table entry of interest, change the color value.
    - **Delete**: To delete a value / color pair from the list, first select the table entry then click delete.

2.16.2.1.13 Gauge element

The Gauge display element shows a numeric parameter value as a horizontal bar in an entry field like frame. The gauge element is capable to adjust the scale factor for the gauge

automatically from the parameter's range definition. Alternatively the scale parameters may set explicitly.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label**: The label text is drawn above the element.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Specify range**: Check this checkbox to define the range which is displayed by the gauge element.
  - **min value**: The minimum value of the displayed range.
  - **max value**: The maximum value of the displayed range.
- **Specify thresholds**: Check this checkbox to define the threshold values which are used for RGR and GYR color schemes.
  - **min thresholds**: The minimum value of the threshold range.
  - **max thresholds**: The maximum value of the threshold range.
- **Graph color**: The gauge element knows three color schemes, allowing to change the bar color dynamically with the monitored value. *Please note, unless you specify min/max thresholds for the monitored value, only the fixed color mode is available.*
  - **Fixed**: The bar is displayed with the color defined with in the above color filed.
  - **R-G-R (red, green, red)**: The bar is displayed green while the value is between the minimum and maximum thresholds. If the value is outside the limits, the bar is displayed red.
  - **R-Y-G (red, yellow, green)**: The bar is displayed red while the value is below the minimum threshold value. It changes to yellow if the value is between the minimum and maximum thresholds. If the value exceeds the maximum threshold, the bar color changes to green.
  - **G-Y-R (green, yellow, red)**: The bar is displayed green while the value is below the minimum threshold value. It changes to yellow if the value is between the minimum and maximum thresholds. If the value exceeds the maximum threshold, the bar color changes to red.
- **show ticks**: check this to make the element show scale ticks vor the min/max and threshold values below the gauge.
- **show ticks with labels**: With this mark checked, below the gauge element labeled ticks are shown for the min/max and threshold values. (requires "show ticks"). Bar graph elements with this option enabled should be configured with a width that is sufficient to

show the scale labels without overlap.

2.16.2.1.14 Chart element

The (strip) Chart display element shows a strip chart of a numeric parameter. The chart advances with a constant speed of 1 pixel / second. The default y-scale is 1/division but may be changed by clicking to the menu button in the chart on top right corner.

By default, the strip chart element lets the y-scale offset follow the displayed value that the recent measurement samples are shown in the diagram. This behavior is optimized for applications where the strip chart shall indicate a 'trend' for the displayed value, using an element height of only 50 pixels or less.

Optionally you may disable this variable scaling by defining fixed scale values in the 'Text / Image Name' field. With this fixed y-axis scaling an additional threshold check may be added, turning the chart background to red if the actual value exceeds the defined limits. When used with limit checking, the height of the chart should be at least 100 pixels.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.
- **Label**: The label text is drawn above the element.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **Color**: The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Mode**: Selects the display mode of the chart element. Four modes are available:
  - **Auto scale**: This is the standard display mode. The strip chart aligns the reference value (the medium display line) in a way that every new display point is shown on this line. The initial scale is 1 unit/div.
  - **Fixed scale**: Works like the auto scale mode, but the scale value gets initialized with a user defined value.
    - **Scale**: The initial scale value used with the 'floating, fixed scale' mode.
  - **Fixed range**: The min/max values to display are defined explicitly, there is no

automatic reference level alignment with this mode.

- **min value**: The minimum value to display for the fixed range display modes.
- **max value**: The maximum value to display for the fixed range display modes.

- **Fixed thresholds**: It is like the above mode, but additionally there are min/max thresholds defined. If the actual value of the monitored parameter, the display background changes to red.

  - **min value**: The minimum value to display for the fixed range display modes.
  - **max value**: The maximum value to display for the fixed range display modes.
  - **min threshold**: The lower threshold value for the "fixed range & thresholds" mode.
  - **max threshold**: The upper threshold value for the "fixed range & thresholds" mode.

2.16.2.1.15 Spectrum element

The Spectrum Display element embeds the spectrum display of a spectrum analyzer device in the screen. The display may be scaled to an almost arbitrary size, however the following limitations apply:

- The annotation labels which reflect the actual spectrum analyzer settings are not scaled with the display element. If the element is very small, the labels may overlap and become unreadable.
- Resizing the spectrum display element is only possible in certain steps, the grid behind the spectrum curve is always made up of 10*n + 11 pixels in one dimension. The screen editor software knows about this, snaps the size of the element to the next (smaller) valid size after you release the mouse button.

The attributes listed below may be configured to customize a display element of this type:

- **Device name**: The name of the spectrum analyzer device with MNC name (MNC.devicename) to operate.
- **Label**: The label text is drawn above the element.
- **Privilege level**: The privilege level necessary to operate the spectrum analyzer device.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
  - **Color**: The color attribute of a element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.

2.16.2.1.16 Target list element

The Target List screen element lets you embed the list of targets of a SatService-ACU-ODM

antenna controller in the screen. Targets may be recalled (which moves the antenna to the stored position and sets the tracking parameters associated with this target), saved or deleted.

Please note, that the ODM Target List screen element only works with SatService-ACU-ODM antenna controller device type, other antenna controllers are not supported.

The attributes listed below may be configured to customize a display element of this type:

- **Device name**: This parameter is interpreted differently depending on the context where the ODM Target List screen element resides:
  - When placed in a user defined screen or in the main screen of the application, 'device name' must be set to the name of the ODM device it shall refer to.
  - When placed in the device screen of another device which defines a configuration variable with the antenna controller device name, the name of this configuration variable must be entered as the 'device name'. Finally, when used in the device screen of the ODM device itself, 'device name' must de set to '@'
- **Privilege level**: The privilege level necessary to operate the target list device.
- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.
  - **Enable ID**: This field defines the ID for the enabling parameter.
  - **Enable value**: The value belonging to the parameter above. The actual value of the parameter

2.16.2.1.17 XY chart element

This element shows the relation of two numeric variables in an X/Y diagram, featuring a 'track' which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.

The X/Y chart display may be scaled to an almost arbitrary size, however the following limitations apply:

- The annotation labels which reflect the actual display settings are not scaled with the display element. If the element is very small, the labels may overlap and become unreadable.
- Resizing the X/Y chart display element is only possible in certain steps, the grid behind the curve is always made up of a number pixels in one dimension which is divisible by the configured number of diagram divisions without remainder. The screen editor software knows about this, snaps the size of the element to the next (smaller) valid size after you release the mouse button.

The attributes listed below may be configured to customize a display element of this type:

- **MessageID(x) message ID (y)**: The message IDs of the parameters to show.
- **Label**: The annotation label displayed above the X/Y chart.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the text shown in the parameter field itself. The

label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
    - **Color**: The color of the label displayed above the X/Y chart. Colors may be specified by using a hexadecimal RGB notation. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- **Chart settings**
    - **Divisions**: The number of divisions shown in the diagram for both directions. You may enter arbitrary values here, but to achieve some readability, you are encouraged to us common values like 2 ('hair cross'), 4 or 10.
    - **Interval**: The update time interval for the display in seconds. 0.1 means to add every 100msec a new value to the display and remove the oldest value from the buffer at the same time.
    - **Buffer size**: The display maintains a "first in first out" buffer of a size defined with this parameter. The buffer provides a short time memory the display shows as a trace of past values. Values in the range 100-300 are a good choice, larger values may slow down the client application. Please note, that the buffer gets cleared when the window is closed.
- **Origin and scale**
    - **x origin y origin**: The origin values refer to the center of the diagram. Using an even number of divisions helps to identify the diagram center as the cross point of the middle grid lines
    - **x scale y scale**: The scale values are per division. with x origin = 0.0 and x scale = 1.0 an x value of 1.0 gets displayed one division right of the diagram center.
- **Monitor limits**: With this checked, the display monitors the actual X/Y values to be within the limits defined below. The limit values are shown as a dark red rectangle. When the while the actual X/Y values exceed the limits, the diagram background becomes red.
    - **min x value, max x value, min y value and max y value**: The limit values for X and Y to be checked.

2.16.2.1.18 Thumbnail icon element

The Thumbnail Icon element lets you display a thumbnail of the video actually processed by a device like a an encoder, decoder or gateway. The displayed icon is a static image, updated every couple of seconds.

The attributes listed below may be configured to customize a display element of this type:

- **Image URL**: The URL where to fetch the image.
- **Reload time**: The interval when the image shall be reloaded (seconds)
- **URL type**: One of PLAIN or ADVANCED. With PLAIN the URL is used as it is, with ADVANCED CGI parameters for the actual time and the image width and height are appended to the URL.

REMARKS

- The device to get the thumbnail images from must support this feature.
- The device to get the thumbnail images from must be accessible in the network from the client's point of view.

- Thumbnail Icons are - when resized by mouse drag in the GUI editor - forced to 16:9 ratio. If another image ratio is required, image width and height must be entered in the dialog shown above. in PLAIN mode, the image received from the device gets scaled to fit the screen element size, in ADVANCED mode no scaling is done as the software queries the image already in the correct size from the device.

2.16.2.1.19 Switch element

The Switch Icon display element is a special version of the Device Icon element which may be used to visualize the position of a switch in a user interface screen designed as a block diagram. The switch icon has all capabilities of a plain device icon display element. The context menu shown with this right mouse button additionally contains an option to toggle the switch position. The switch icon element -- unlike the plain device icon element -- does not support user defined images.

The attributes listed below may be configured to customize a display element of this type:

- **Device name**: The name of the device this element stands for. You also may enter the complete ID of the parameter which controls the switch position for devices which manage more than one switch or use a non-standard switch position parameter name.
- **Icon**: Select the shape of the icon from the given switch symbols or a user defined switch. .ts user defined switchThe (base-) name of a set of userdefined switch icons. See below how to use your own switch icons.
- **Privilege level**: The privilege level necessary to toggle the switch position. To change the device mode (OPERATIONAL, OUT-OF-SERVICE), at least a privilege of 100 is necessary, or the value set here if this is higher.
- **Touch screen mode**: Selecting this option makes the switch icon behave differently, optimized for touch screen usage. You may toggle the switch position by touching the icon twice. This first time you touch it, the icon shows a turquoise ball in the upper left corner. This ball disappears after 2 seconds. If you touch the icon a second time before the turquoise ball disappears, the switch is actuated. There is no right mouse button context menu in this mode, no way to go into the device screen or set the device OUT-OF-SERVICE.
- **Font**: Font contains two options:
  - **Font**: The font attribute applies to the device name, too.
  - **Color**: The color attribute of a parameter element sets the color of the device name shown with the icon.
- **Conditionally enable widget**: Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this to activate this feature.
  - **Enable ID**: This field defines the ID for the enabling parameter.
  - **Enable value**: The value belonging to the parameter above. The actual value of the parameter
- **Query before toggling switch**: Check this mark to make the element show a query before a parameter gets actually commanded.
  - **Query text**: The query text to be shown in the pop-up window. You may leave this

field empty, the program uses a standard query text in this case. In the question text, placeholders may used for two values: Any occurrences of the pattern `$P` get replaced by the parameter name (message ID). Any occurrences of the pattern `$V` get replaced by the new value to set.

Remarks

Configuring a confirmation question as described above, only affects the 'Toggle position' function provided by the switch icon's right mouse context menu. Setting the switch position from the device dialog always works without a confirmation request.

User defined switch icons

The sat-nms software comes with 6 predefined switch icons. You may add your own icons if none of the predefined switches matches your needs.

For a user defined switch you have to create a set of ten PNG image files / icons. Each icon shows one combination of switch position and device state. All icons of a set must be of the same size, the files must be located in the *images* subdirectory of the sat-nms server installation and they must follow the naming scheme described below.

The file name of a switch icon consists of the user defined name, followed by a dash and a 2-character status code. All switch icons must be PNG images and end with the file suffix ".png" (lower case). The first character of the status code reflects the switch position, the second one the device's fault/operation state. The following codes are defined:

pos.	character	description
1	A	switch is in position A (or OFF)
1	B	switch is in position B (or ON)
2	N	switch device is in normal operation, no fault is pending
2	W	switch device shows a warning
2	F	switch device shows a fault
2	S	switch device is set FAULT-SUPPRESSED
2	O	switch device is set OUT-OF-SERVICE

Combining the two switch positions with five device status codes results in totally 10 icons which show all possible states of a switch. If you create a switch named "myswitch", the files would be:

myswitch-AN.png myswitch-AW.png myswitch-AF.png myswitch-AS.png myswitch-AO.png myswitch-BN.png myswitch-BW.png myswitch-BF.png myswitch-BS.png myswitch-BO.png

Replacing the predefined icons

In in your sat-nms installation mostly user defined switch symbols are used, you may replace some or all of the predefined switch symbols offered by the Switch Icon dialog with your favorite icons. To configure this, edit the file "client.properties" in the base directory of the sat-nms server installation and add some or all lines of the following:

gui.editor.predefinedSwitch.1=myswitch1 (replace myswitch1 by the name of the icon set to use) **gui.editor.predefinedSwitch.2=myswitch2 gui.editor.predefinedSwitch.3=myswitch3 gui.editor.predefinedSwitch.4=myswitch4 gui.editor.predefinedSwitch.5=myswitch5 gui.editor.predefinedSwitch.6=myswitch6**

Please note, this does not replace / delete the factory icons. Screens which make use of the factory switches will still use them as before and you are still able to edit screens with factory switch icons by explicitly define their names in the *user defined switch* field. The names of the factory switch icons are *wgswitch* , *wgswitch-mirrored* , *cxswitch* , *cxswitch-mirrored* , *lswitch* and *rswitch* .

User defined switch icons may be of any size, even larger than the factory icons. When used as predefined switch icons, such large icons will show up in the dialog with their upper left corner only. In the screen the icons gets displayed with it's full size.

2.16.2.1.20 AzEl element

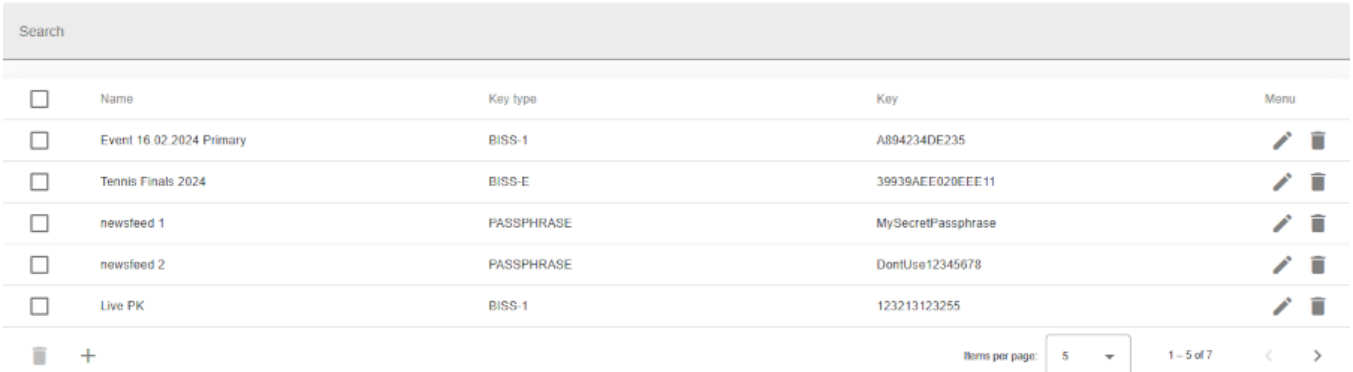
The AzElElement shows the tracking history of an antenna controller as a cloud of points in a elevation over azimuth coordinate system. Actually only SatService antenna controllers provide the tracking history data for this screen element.

The attributes listed below may be configured to customize a display element of this type:

- **Message ID**: The message ID addresses the parameter the element shall display or edit. The message ID consists of the MNC name, device name followed by a colon and the name of the parameter.ANT.11.XMIT-1.tx.on for example addresses the variable tx.on at a device named XMIT-1 at MNC.

2.17 Stream keys

The Stream key is record holds the information about one BISS or SRT key in the database. The Table provides a detailed interface to manage keys. It allows users to view, edit, delete, and create key efficiently.



Search bar

- Located at the top of the table.
- Allows users to filter keys by keywords, such as name, key type and key.

Header row

- You can sort rows in ascending or descending order by clicking on the column header (e.g. name, key, etc.).
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
  - **Location**: The checkbox column is located at the far left of the table.
  - **Purpose**: Allows users to select one or multiple keys for delete key(s).
  - **Functionality**:
    - **Single Selection**: Click on a single checkbox to select an individual row.
    - **Multiple Selection**: Click multiple checkboxes to select multiple rows at once.
    - **Select All**: The checkbox in the header row allows you to select or deselect all rows on all pages.
    - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **Name**: The user defined unique name of stream key.
- **Key type**: The key type, one of 'BISS-1', 'BISS-E' or 'PASSPHRASE'.
- **Key**: The stored key in database.
- **Functions**: Action icons for managing the key:
  - **Edit**: Pencil icon to modify/edit the key.
  - **Delete**: Trash can icon to delete the key.

Bottom toolbar

- **Delete selected keys**: A button to delete selected keys/rows from checkbox column.
- **Create key**: + button is used to create new stream key.
- **Pagination controls**: Allows users to set the number of items displayed per page and

navigate between pages.

2.17.1 Features

Create key

- Click the + button at the bottom of the table to add a new event.
- Input the required details.

Edit key

- Click the *pencil icon* in the Functions column to modify key details.
- Adjust the settings and save.

Delete event

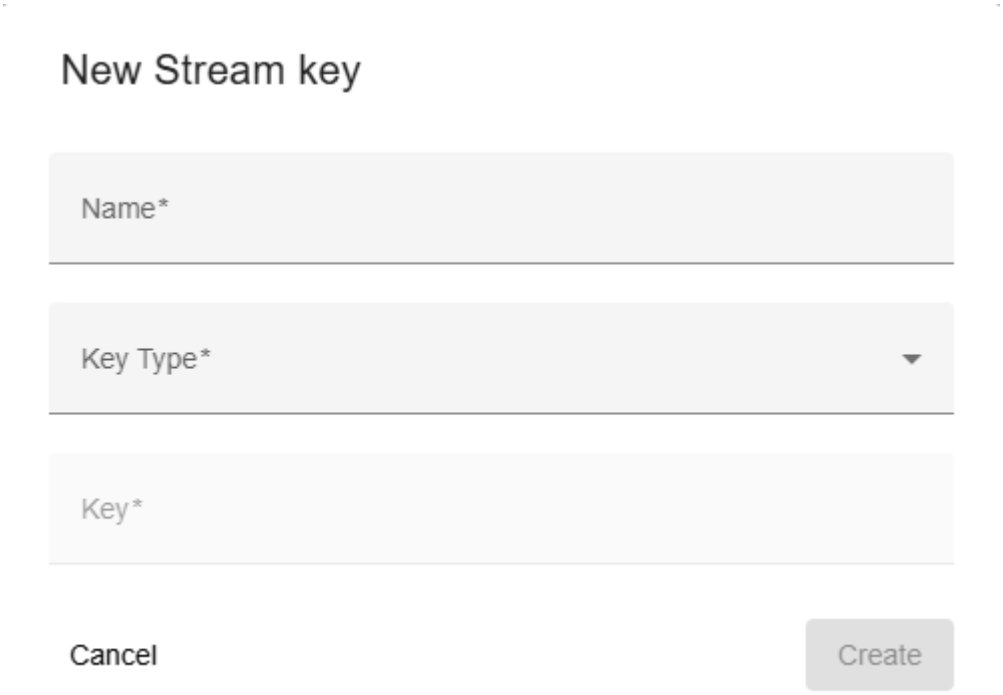
- Click the *trash icon* in the Functions column to delete an key.
- Confirm the action in the pop-up dialog to delete the key.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.17.2 Dialogs

Stream key add/edit dialog



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new key or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new stream key, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Name**: The user defined name of this stream key. This name must be unique, as the operator selects the key according to this name.
  - **Key type**: The key type, one of *BISS-1*, *BISS-E* or *PASSPHRASE*.
  - **Key**: The key value associated with the id and name in this record. For *biss* keys this is a string entirely consisting of the hexadecimal characters 0123456789ABCDEF and it is either 12 or 16 characters long. For other key types, the key is a free text.
- **Actions**:
  - **Create/Save**:
    - For new stream key, this creates the event with the provided details.
    - For existing keys, this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete kex confirmation dialog

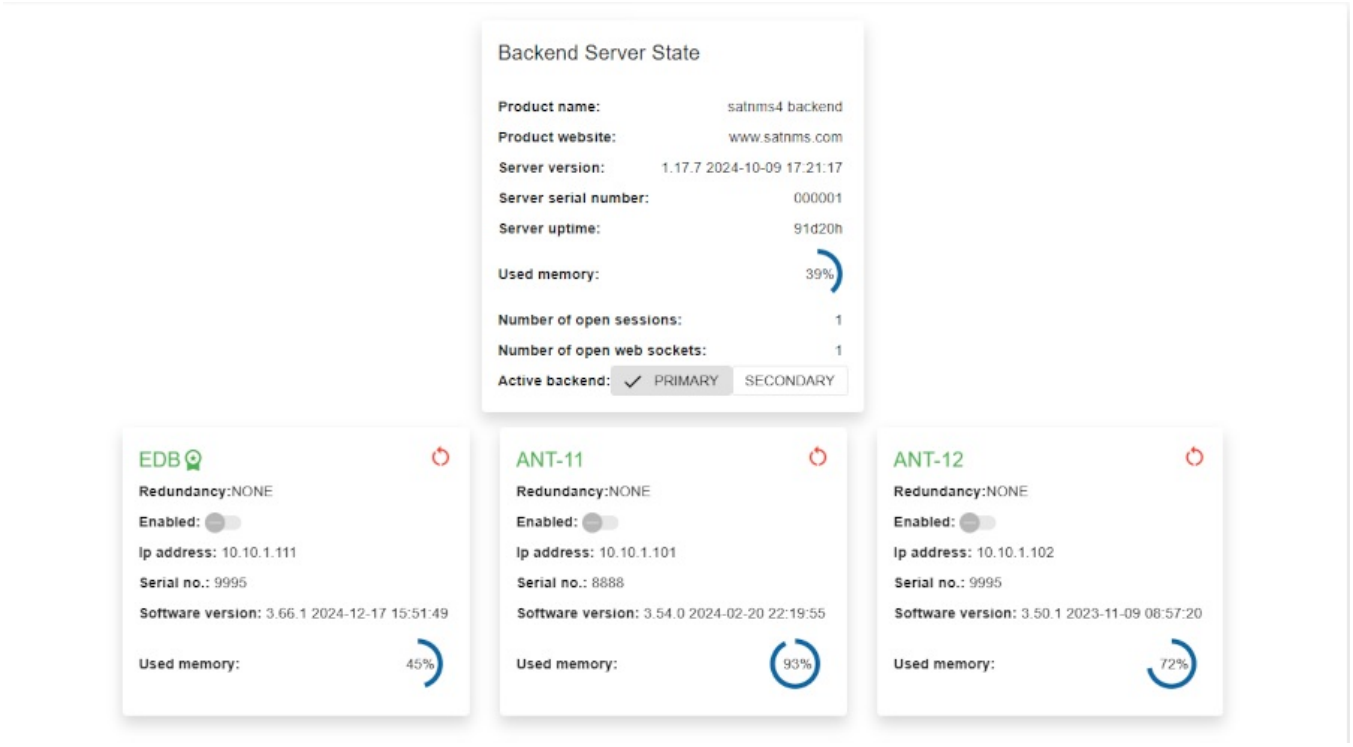
- **Trigger**: Opens when you click the trash icon for an key from menu column or trash icon from bottom toolbar .
- **Content**: Asks the user to confirm whether they want to delete the selected event(s).
- **Actions**:
  - **Yes**: Deletes the event(s) permanently.
  - **Cancel**: Cancels the deletion action.

2.18 System status

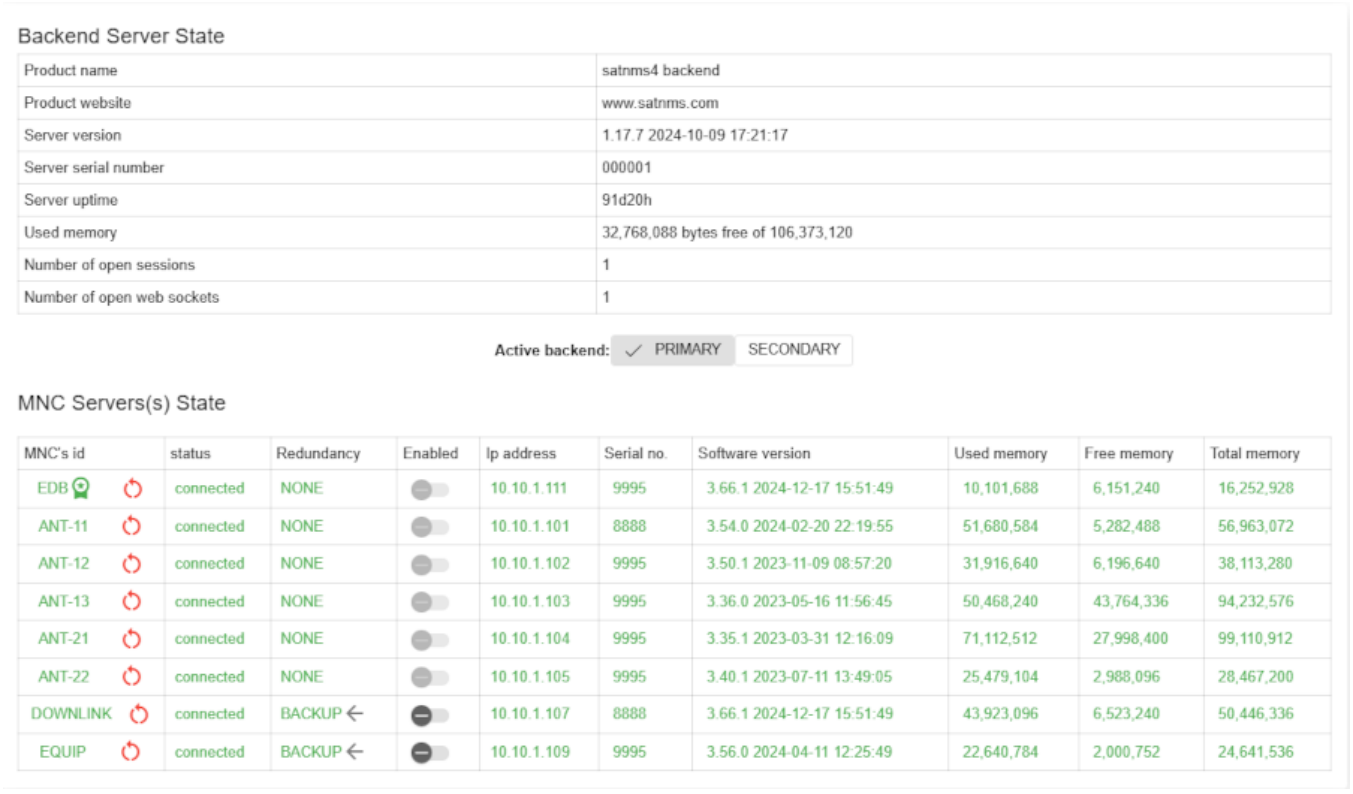
This page gives you status information about the backend server.

1. **Title**: Title of page.
2. **View options**: At the top right of the page are view options.
   - Grid view (default)
   - Table view.

2.18.1 Grid view



2.18.2 Table view



Backend Server State

Product name	satnms4 backend
Product website	www.satnms.com
Server version	1.17.7 2024-10-09 17:21:17
Server serial number	000001
Server uptime	91d20h
Used memory	32,768,088 bytes free of 106,373,120
Number of open sessions	1
Number of open web sockets	1

Active backend: PRIMARY SECONDARY

MNC Servers(s) State

MNC's id	status	Redundancy	Enabled	Ip address	Serial no.	Software version	Used memory	Free memory	Total memory
EDB	connected	NONE		10.10.1.111	9995	3.66.1 2024-12-17 15:51:49	10,101,688	6,151,240	16,252,928
ANT-11	connected	NONE		10.10.1.101	8888	3.54.0 2024-02-20 22:19:55	51,680,584	5,282,488	56,963,072

2.18.3 Common functions and details

Backend server state

- **Product name**: The name of product.
- **Product website**: The SatService website URL.
- **Server version**: The software version actually running.
- **Server serial no.**: The software serial number.
- **Server uptime**: The server uptime.
- **Used memory**: The memory usage of the backend.
- **Number of open sessions**: The number of open sessions.
- **Number of open web sockets**: The number of open (message) websocket connections.
- **Active backend**:
  - The name of the backend which actively controls M&C redundancy switching in a redundant backend configuration.
  - **Functionality**: Clicking on name will change the active backend.

MNC information

Below you will find information about MNC.

- **MNC name**:
  - The name of the M&C.
  - If there is a medal icon that means that MNC is an primary MNC (e.g. EDB)
  - **Restart MNC**: On the right hand side you can restart an MNC by clicking on red reload button.
- **Redundancy**:
  - Shows the state of the redundancy control for this M&C.
  - **Functionality**: Switch from main to backup or backup to main
- **Enabled**: Flag if this redundancy is enabled or not.
- **Ip address**: The IP address of the M&C server as defined in the backend configuration file.
- **Serial no.**: The software serial number.
- **Server version**: The software version actually running.
- **Used memory**:
  - The memory used by MNC.
  - On hover it shows total-, used- and free-memory.

2.18.4 Features

Restart MNC

- Clicking on the red reload button (grid or table view) restarts the MNC.

Active backend

- If you click on the backend name below or near the active backend text, the active backend name is changed.

Switch to main/backup

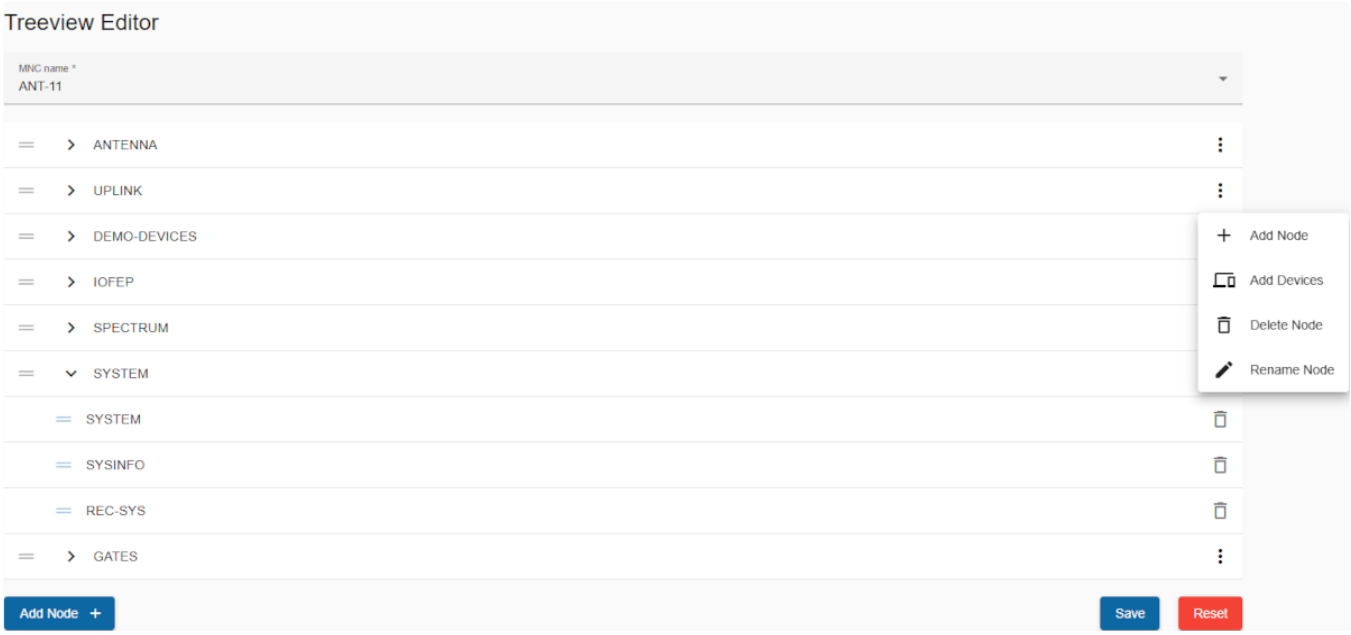
- Click on the arrow buttons (left or right) next to *Redundancy* to change MNC from *Backup to Main or Main to Backup*.

Toggle redundancy

- You can activate or deactivate redundancy using the slider under *Enabled*.

2.19 Treeview editor

The Treeview editor lets you define or modify the tree / subsystem hierarchy used by the M&C Tree View.



Title: Title of page.

MNC name: Below the title, you must select an option from the drop-down list to start editing.

Tree structure

- **Subsystem/Parent node**: are displayed as the top-level entries in the tree. Each parent node can have child nodes nested underneath. Subsystem/Parent nodes can be expanded (▼) or collapsed (►) to hide or reveal their child nodes.
    - **Drag handel**: Appears to the left of the subsystem/parent node name, allowing the node to be reordered or moved into another subsystem/parent node.
    - **Node name**: Displays the name of the subsystem/parent node.
    - **Context-menu (⋮)**: Located to the right of the node name, this menu provides the following options:
        - **Add Node**: Create a new subsystem node under the selected node.
        - **Add Devices**: Attach specific devices to the selected node.
        - **Rename Node**: Change the name of the selected subsystem/parent node.
        - **Delete Node**: Remove the subsystem/parent node and all its children.

- **Device/Child node**: are displayed indented beneath their respective subsystems or parent nodes and cannot exist at the top level (as subsystem). They must always belong to a subsystem.
    - **Drag handel**: Appears to the left of the device/child node name, allowing the node to be reordered within the same subsystem/ parent or moved into another subsystem/parent node.
    - **Node name**: Displays the name of the device/child node.
    - **Delete button**: A trash bin icon on the right allows for quick deletion of the device/child node.
- **Drag and Drop**: Subsystem/Parent nodes and devices/child nodes can be dragged and dropped using the drag handles:
    - **Reordering**: Rearrange nodes within the same subsystem/parent.
    - **Moving**: Move nodes between different subsystems/parents.
    - **Error**: If something is not correct, the snack bar (error) would be displayed with the description of the error at bottom of the page.

Bottom toolbar actions

The Save and reset button is deactivated if no changes have been made.

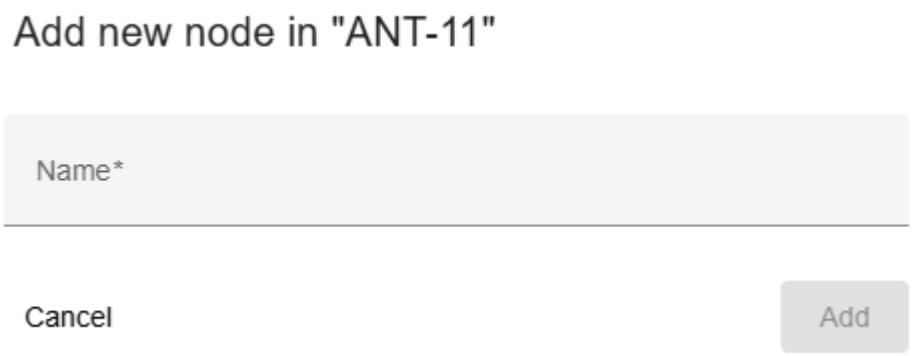
- **Add node**: Use the *Add Node +* button at the bottom of the editor opens a dialog to quickly add a new subsystem/parent node to the tree.
- **Save**: Saves all changes made in the editor. If you have not saved the changes and accidentally leave the editor, a confirmation dialog will appear in which you must give your consent to leave the editor/page.
- **Reset**: Revert the tree structure to its original state.

2.19.1 Functionality

1. **Drag-and-Drop**: Users can drag and drop rows to rearrange the hierarchy dynamically.
2. **Reset changes**: If you made a mistake and want to have old state just click on reset changes to start again from first state.
3. **Unsaved changes**: If you have not saved the changes and accidentally leave the editor, a confirmation dialog will appear in which you must give your consent to leave the editor/page.

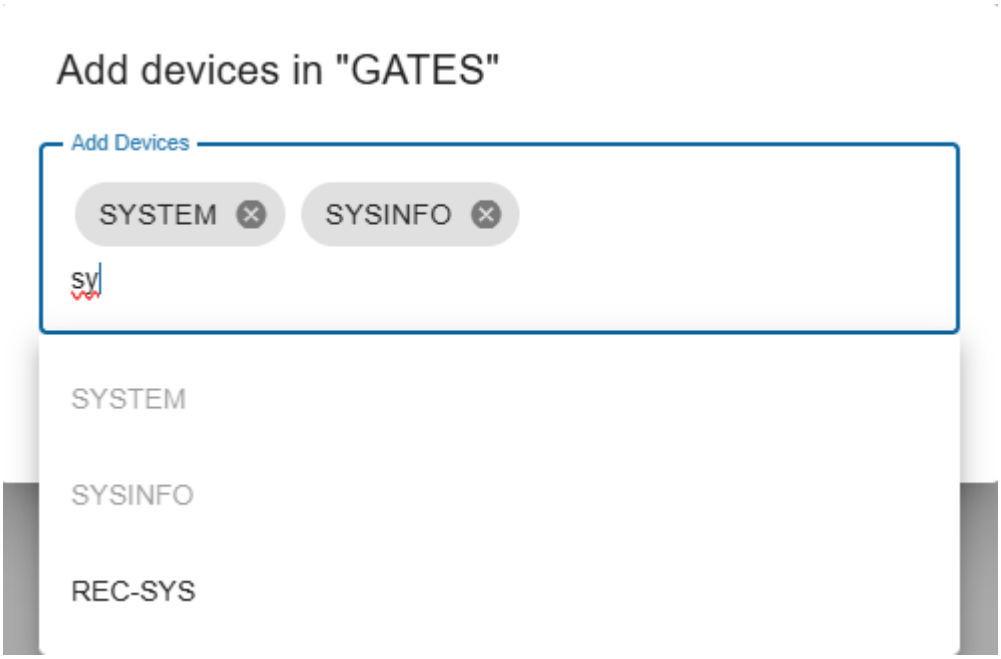
2.19.2 Dialogs

Add/rename node/subsystem



- **Trigger**:
  - when you click on the "Add node +" button on the bottom to create new subsystem/parent node or
  - an on *pencil icon* to rename node from context menu
  - The dialog title clearly indicates whether you are creating a new node on top level or under other node, renaming an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Name**: The name of the subsystem or node. It must be unique compared to other subsystem/node names.
- **Actions**:
  - **Add/Rename**:
    - For new node, this creates the node with the provided name and add devices dialog will be open.
    - For existing node, this renames subsystem/node.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

Add devices



- **Trigger**:
  - when you click on the "Add devices" button from context menu of selected subsystem/parent node.
  - The title of the dialog clearly indicates in which subsystem/parent node you are adding devices to provide clarity about the action being performed.
- **Fields**:
  - **Add devices**:
    - **Device filtering**: The input field includes a dropdown that shows a list of available devices. As the user types in the input field, the list is automatically filtered to match the entered text. Once you have completed the device selection, simply click outside the dialog to hide the dropdown.
    - **Adding Devices**: When a device is selected from the dropdown, it appears as a small tag (chip) displayed above the input field. Users can continue selecting multiple devices, with each device added as a separate tag. Selected device(s) are disabled for the clarity. Each tag includes a small *close (×) icon*. Clicking on the close icon removes the corresponding device from the selection.
- **Actions**:
  - **Add**: Add device(s) to the selected subsystem/parent node.
  - **Cancel**: Closes the dialog without saving.

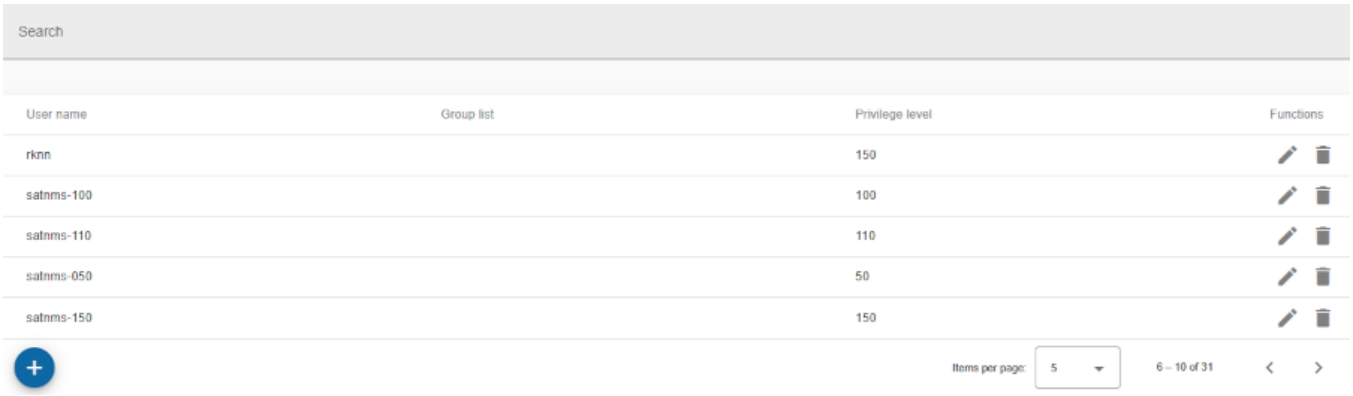
Confirmation dialog

- **Trigger**: Opens when you click the
  - delete node from context menu
  - Trash icon from device/child node.
  - Reset button
  - Leaving the page if there are unsaved changes.
- **Content**: Asks the user to confirm the action, depending on where you trigger the dialog.

- **Actions**:
  - **Yes**: Confirm the action.
  - **Cancel**: Cancels the action.

2.20 User management

The user management lets you manage the list of users which are allowed to operate the software. You need to be a administrator with privilege level 150 or higher to access the user management page.



Search bar

- Located at the top of the table.
- Allows users to filter keys by keywords, such as name, key type and key.

Header row

- You can sort rows in ascending or descending order by clicking on the column header.
- Sorting is applied to the entire dataset, not just the current page.
- The active sort order (ascending or descending) is typically indicated by an arrow or icon near the column name.

Table columns

- **Checkbox column**:
  - **Location**: The checkbox column is located at the far left of the table.
  - **Purpose**: Allows users to select one or multiple rows for delete row(s).
  - **Functionality**:
    - **Single Selection**: Click on a single checkbox to select an individual row.
    - **Multiple Selection**: Click multiple checkboxes to select multiple rows at once.
    - **Select all**: The checkbox in the header row allows you to select or deselect all rows on all pages.
    - **Delete**: After selecting events, delete action on bottom toolbar can be performed for all selected items.
- **Username**: The login name of the user.
- **Group list**: Group list in which is user assigned.

- **Privilege level**: The privilege level level determines whether a user is only allowed to control some basic aspects of the M&C system or whether the operator is allowed to change everything. Higher numbers mean higher privileges or more comprehensive control.
- **Functions**: Action icons for managing the user:
  - **Edit**: Pencil icon to modify/edit the user.
  - **Delete**: Trash can icon to delete the user.

Bottom toolbar

- **Delete selected users**: A button to delete selected users/rows from checkbox column.
- **Create user**: + button is used to create new user.
- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.20.1 Functionality

Create user

- Click the + button at the bottom of the table to add a new user.
- Input the required details.

Edit user

- Click the *pencil icon* in the Functions column to modify user details.
- Adjust the settings and save.

Delete user

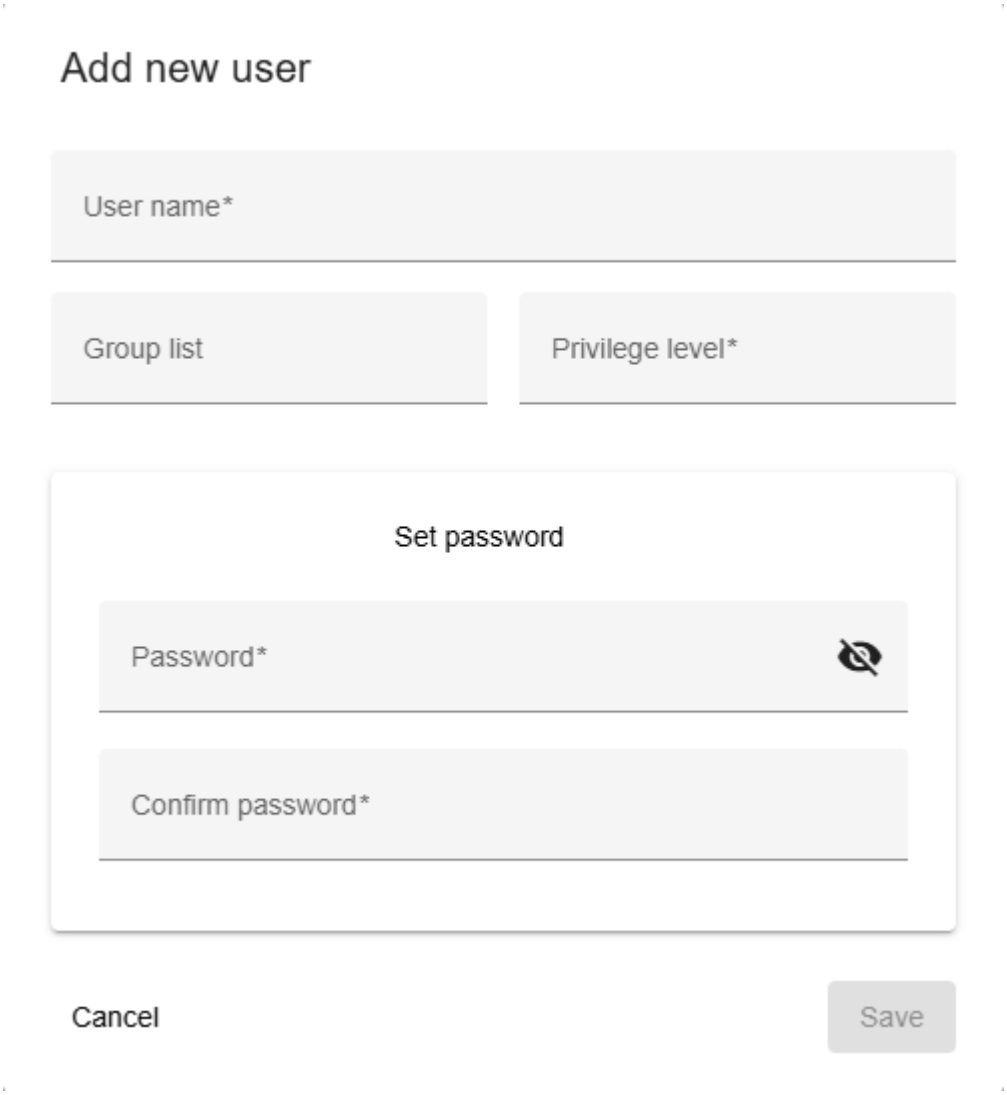
- Click the *trash icon* in the Functions column to delete an user.
- Confirm the action in the pop-up dialog to delete the user.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.20.2 Dialogs

Add/edit user dialog



- **Trigger**:
  - when you click on the "+" button on the bottom toolbar to create new user or
  - an on *pencil icon* to edit in the menu column
  - The dialog title clearly indicates whether you are creating a new user, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Username**: The login name of the user with which the user log in.
  - **Group list**: User group list.
  - **Privilege level**: Set privilege level for controlling user access. Must be greater then 1.
  - **Set password/ Change password**: If you want to edit or reset an existing user password, change the password displayed instead of *Set password* and simply expand it to change password.
    - **Password**: Set use password.
      - **Show password**: Click on visibility/eye icon to show or hide (default) password.
    - **Confirm password**: Confirm password.

- **Actions**:
  - **Save**:
    - This saves modifications.
    - If an error occurs in the input fields, the button is deactivated.
  - **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column or trash icon from bottom toolbar.
- **Content**: Asks the user to confirm whether they want to delete the selected user(s).
- **Actions**:
  - **Yes**: Deletes the user(s) permanently.
  - **Cancel**: Cancels the deletion action.

2.21 User settings

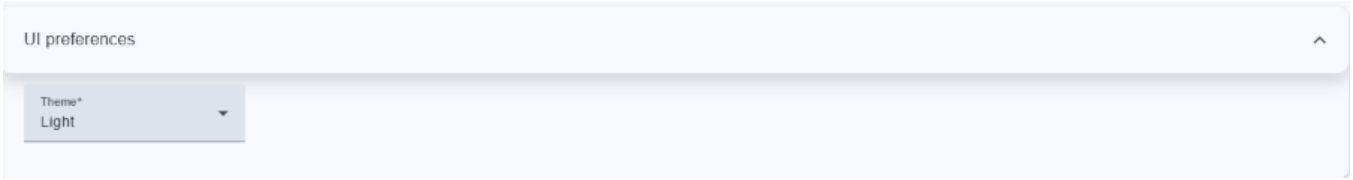
The User Settings page allows users to customize their experience and configure preferences. All changes made on this page are saved directly in the browser's storage or in the Database, ensuring personalized settings persist across sessions.

Title: Title of page.

Save mode: You can save your settings in the browser cache (default) or in the database.*The database or default settings specified by the admin (unless the setting is locked) are overwritten if the user has saved settings in the browser cache.* **Global settings**: Navigate to Global settings (admins only) **Key features**: Clicking on title will expand that section

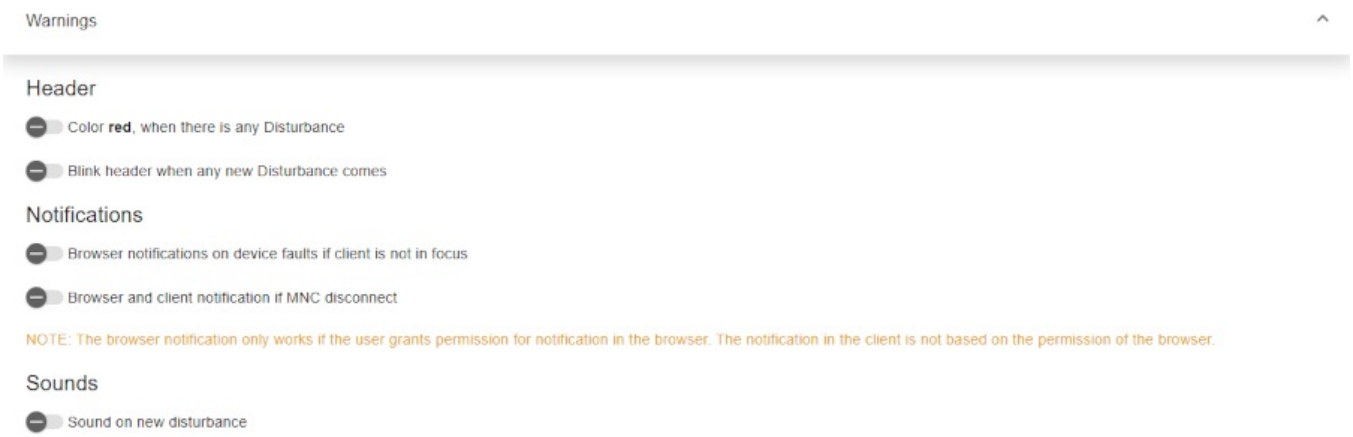
- UI preferences
- Warnings
- Edit take mode
- User screen
- Navigation
- Menu shortcuts
- Table settings

2.21.1 UI preferences



Theme: It an drop-down to choose between light, dark or automatic. Automatic option will adapt your system theme.

2.21.2 Warnings



Top

- Section title
- Icon to expand or collapse section

Header

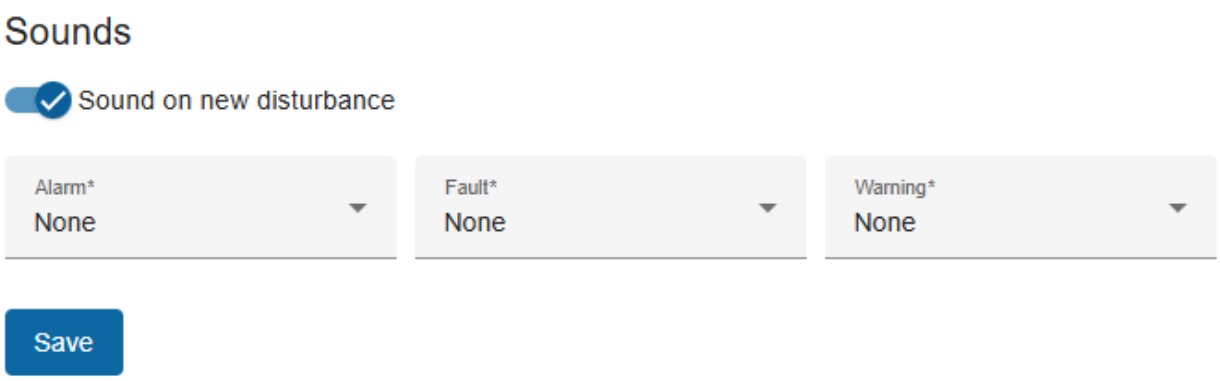
- Color red, when there is any Disturbance
- Blink header when any new Disturbance comes

Notifications

- Browser notifications on device faults if client is not in focus
  - If user client is not in focus or user find hisself in other tab, a notification will informs you. *NOTE: will not work on tablet or phone*
- Browser and client notification if MNC disconnect
  - If an MNC got disconnected you will be informed either with web browser notification or with snackbar.

Sounds

- Sound on new disturbance

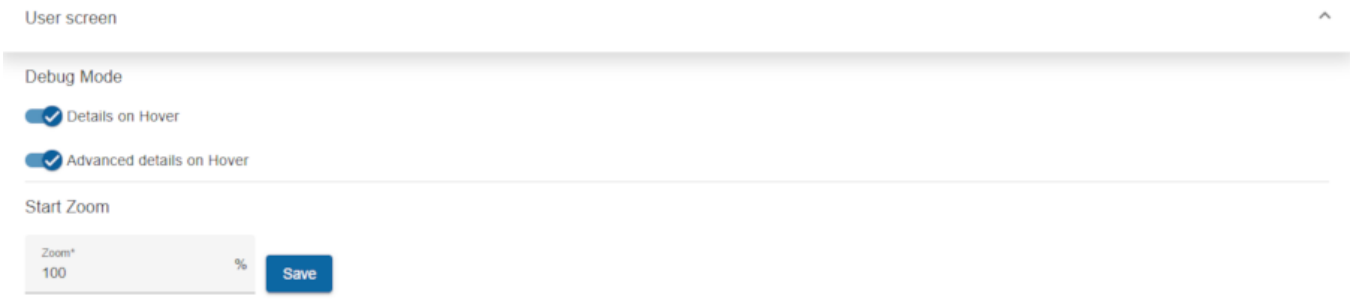


- If checked you can set different sounds for different warnings.
- **Save**: To save settings.

2.21.3 Edit take mode

Configure the edit take mode for device windows. If turns on, device window parameters are disabled. You can click on edit button to start editing parameters on device window and clicking on take button will save the edited values.

2.21.4 User screen



Debug mode

Enables additional debugging features, such as hovering over elements to display detailed information for debugging purposes.

- **Details on hover**: display some information in the bottom left corner when the mouse pointer is moved (hovered) over a display element (e.g. display element type, messageId, value and device mode) on the user screen-
- **Advanced details on hover**: same as *Details on hover*, but this displays more information.

Start zoom

Users can define a custom zoom level (in %) for the user screens. Once set, the user screen

will always display at the specified zoom level.

- **Zoom**: Type wished value. Default is 100%.

Save: Will save the zoom level.

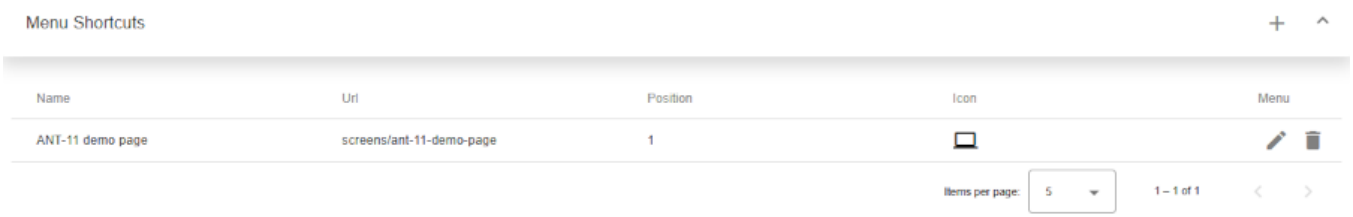
2.21.5 Navigation

Provides the option to set a specific page as the home page for easier navigation after user successfully logged in.

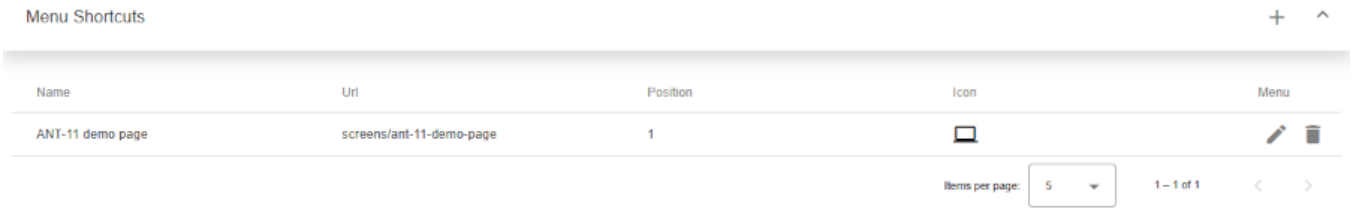
Set default url: Just type your whished url.

Save: Will save the url

2.21.6 Menu shortcuts



Allows users to add custom links under *Shortcuts* in the sidebar with other menus for quick access (in the image above) to frequently used pages or resources.



Top

- Left-side title of table.
- Plus (+) button to create new shortcut.
- Icon button to expand or collapse table

Table columns

- **Name**: The name of the created shortcut.
- **Url**: Saved url of shortcut.

- **Position**: Position of the shortcut.
- **Icon**: Shortcut icon.
- **Functions**: Action icons for managing the shortcut:
  - **Edit**: Pencil icon to modify/edit.
  - **Delete**: Trash can icon to delete.

Bottom toolbar

- **Pagination controls**: Allows users to set the number of items displayed per page and navigate between pages.

2.21.6.1 Functionality

Create shortcut

- Click the + button at the top of the table to add a new shortcut.
- Input the required details.

Edit shortcut

- Click the *pencil icon* in the Functions column to modify shortcut details.
- Adjust the settings and save.

Delete shortcut

- Click the *trash icon* in the Functions column to delete an shortcut.
- Confirm the action in the pop-up dialog to delete the shortcut.

Pagination

- Adjust the number of rows displayed per page using the dropdown menu (e.g., 5, 10, or 25).
- Use the navigation arrows to move between pages of the table.

2.21.6.2 Dialogs

Add/edit shortcut dialog

- **Trigger**:
  - when you click on the "+" button on the top toolbar to create new or
  - an on *pencil icon* to edit shortcut in the menu column
  - The dialog title clearly indicates whether you are creating a new, editing an existing one, ensuring clarity in the action being performed.
- **Fields**:
  - **Menu name**: The name of the menu a user want to have.
  - **Url**: A url on which user want to have quick access.
  - **Icon**: The icon name can be chosen from *Google icons* and should be entered (lower case).

    - As soon as you have selected a icon, a window with the details appears on the right-hand side. Select or write the name of the icon in the *Inserting the icon* area, as in the example above with the red frame.
    - If the icon is not displayed after saving the shortcut, this means that the icon is not available.
  - **Position**: Enter the position of shortcut to have the shortcut in right order.
- **Actions**:
  - **Save**:
    - this saves modifications.
    - If an error occurs in the input fields, the button is deactivated.

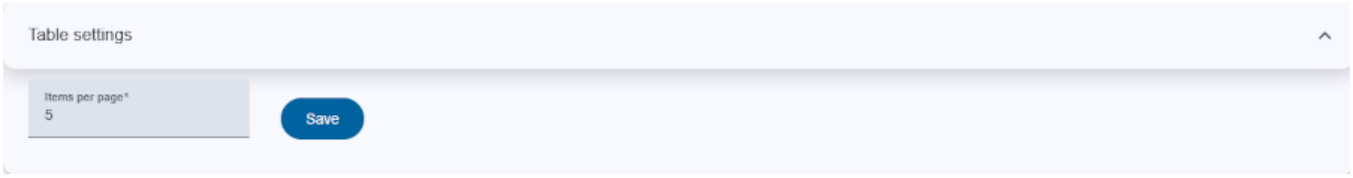
- **Cancel**: Closes the dialog without saving.

On delete confirmation dialog

- **Trigger**: Opens when you click the trash icon for an key from menu column.
- **Content**: Asks the user to confirm whether they want to delete the selected shortcut.
- **Actions**:
  - **Yes**: Deletes the shortcut permanently.
  - **Cancel**: Cancels the deletion action.

2.21.7 Table settings

Provides the option to set settings on tables of the app.



Items per page: Set number items that table should show.

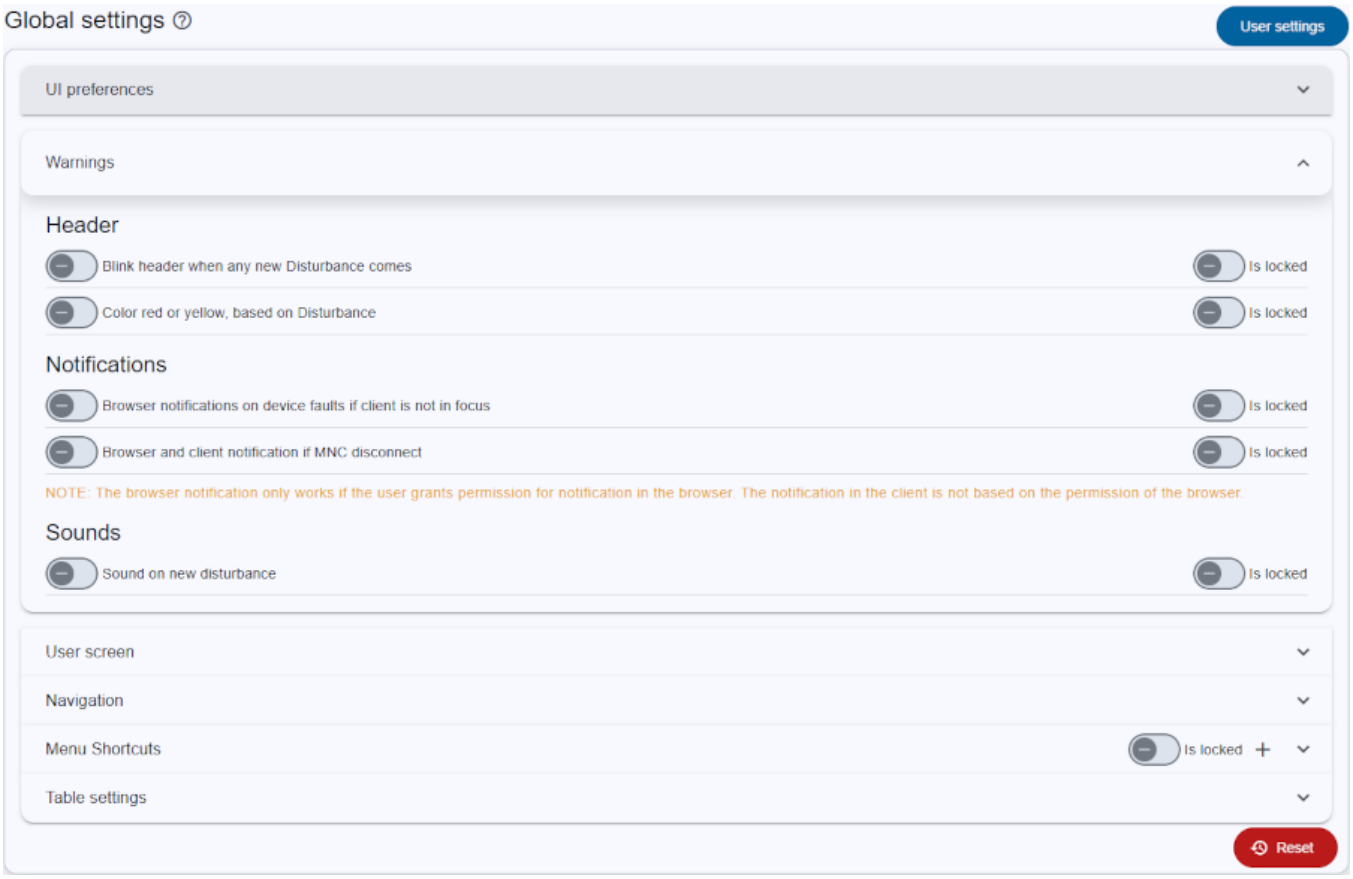
Save: Will save the setting.

2.21.8 Reset

2.22 Global settings

The Global Settings Page allows administrators to define and enforce default configurations across all users in the application. It shares the same structure and layout as the User settings, providing a familiar interface with the added ability to lock specific settings. Only users with administrative privileges can access this page.

Settings configured here act as defaults for users who haven’t explicitly saved their own preferences. Each setting includes a lock toggle. When a setting is locked, users cannot modify it in their personal settings, and the locked value is automatically applied by the application.



2.23 Bottom panel

The bottom section of the webpage, referred to as the Bottom Toolbar, offers quick access to essential features and logs for system monitoring and interaction. The Bottom Toolbar is available throughout the application, ensuring users can quickly interact with features at all times. The bottom toolbar is expandable with selected tab.

It contains the following tabs:

- **Live log**: displays real-time logs and M&C activity.
- **Event report**: Shows a detailed report of recent events in the system.
- **Active Alarms**: Lists all currently active alarms or notifications.
- **Macros**: Provides access to automated scripts or macros.
- **Terminal**: Offers a direct terminal interface for advanced system commands.

2.23.1 Interaction features

Persistent accessibility

- The bottom toolbar is always present and can be accessed from any page in the app.
- Simply hover on the bottom toolbar to reveal the toolbar's resize handle.

Resize handle

- **Drag to resize**: Once the handle is visible, click and drag it upwards to expand the toolbar or downwards to minimize it.
- **Double-Click**: Double-clicking the resize handle will instantly expand the toolbar to full screen and by full screen double-clicking the resize handle minimize the toolbar instantly.

2.23.2 Live log

The Live Event Log window shows the recent event messages as they are received from one of the M&Cs. The Live Event Log window shows the messages in the order of their arrival at the M&C. The window can be resized, scrolled and always shows the last 25 messages.

The sort order of the event list (newest first / oldest first) may be toggled using the*Sort by* dropdown on the right hand side. The default sort order is determined from a parameter set in the "client.properties" file located at the M&C server. Setting the key "gui.eventSortOrder" to "true" or "false" defines the default behavior of the live event log window.

Table columns

- **ID**: The event ID. This is a unique number the software assigns to each event which arrives at the M&C.
- **TIME**: The time stamp when the event was originated
- **NAK**: The 'need acknowledgment' mark. Messages showing a red exclamation mark in this column are fault messages which need to be acknowledged by the operator.
- **PRIO**: The message priority. The message priority decides on the urgency, the message gets delivered from the M&C to the client. It also is a search criteria in the Event Report window. The following priority symbols may appear:
  - : This is an informational message (lowest priority)
  - : This is a fault message (medium priority)
  - : This is an alarm message (highest priority, the MNC tries to deliver this immediately, regardless of the dial timing settings)
- **SOURCE**: The primary message source. This usually is the ID of the MNC which issued the message. Messages marked with 'USER' or 'MNC' in this column.
- **DEVICE**: The secondary message source. This gives a more detailed information about the source of the message. It may be the name of the device in a MNC which caused the event.

- **MESSAGE**: The message text.

Right side toolbar

- **Sort table**: The table content can sort by descending and ascending.
- **Acknowledge all faults**: Acknowledge all faults marked with the red exclamation mark.
- **Acknowledge fault**: This button may appear if you want to acknowledge messages marked with the red exclamation mark. Simply select the row with red exclamation mark with mouse click. The exclamation mark will then disappear and a confirmation message will be added at the end of the log.

2.23.3 Event report

The Event Report window lets you generate filtered reports from the event database maintained by the NMS. This database contains all event (fault) messages issued by the MNCs during the last months (the exact depth of event storage is configurable during system installation).

The event report shown in the table gets automatically updated when you change the time range or apply other filter to display or the sort order. This lets you combine various filter specifications without being interrupted by the generation of intermediate reports.

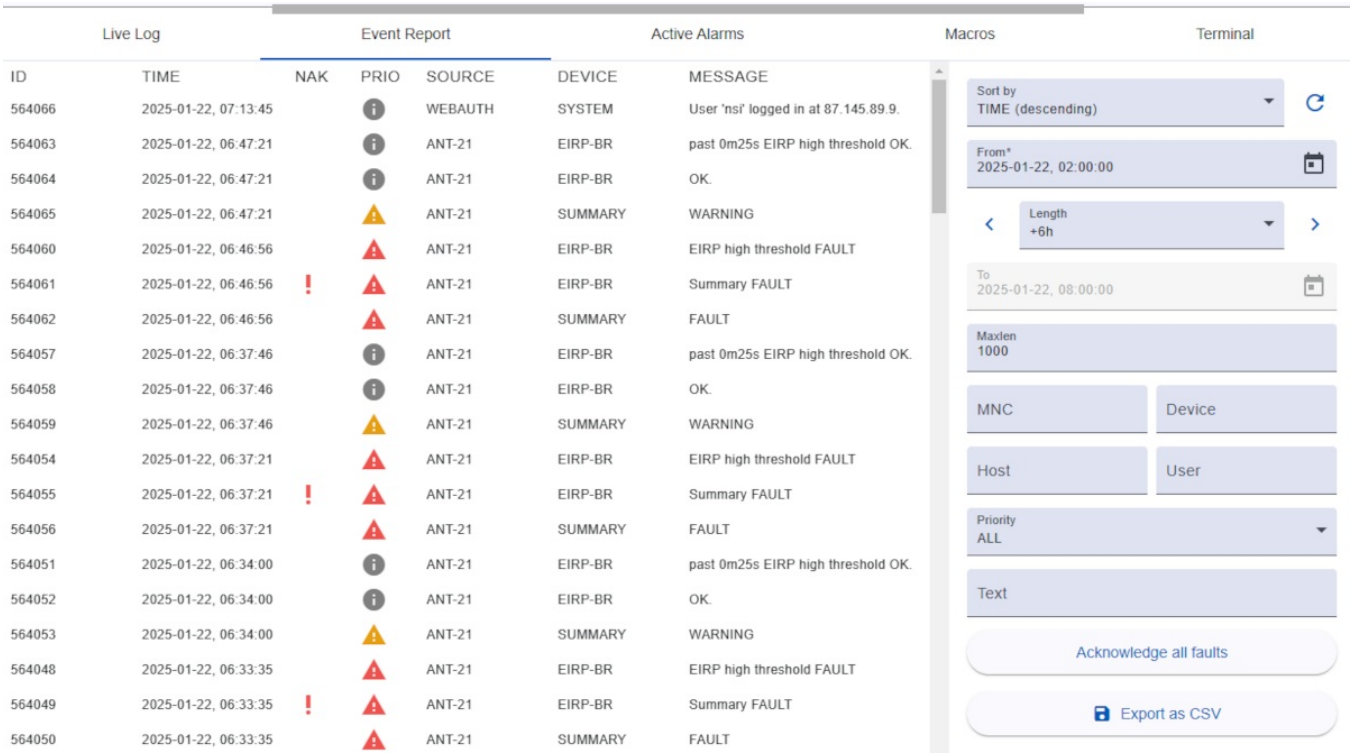


Table columns

- **ID**: The event ID. This is a unique number the software assigns to each event which arrives at the M&C.
- **TIME**: The time stamp when the event was originated

- **NAK**: The 'need acknowledgment' mark. Messages showing a red exclamation mark in this column are fault messages which need to be acknowledged by the operator.
- **PRIO**: The message priority. The message priority decides on the urgency, the message gets delivered from the M&C to the client. It also is a search criteria in the Event Report window. The following priority symbols may appear:
  - : This is an informational message (lowest priority)
  - : This is a fault message (medium priority)
  - : This is an alarm message (highest priority, the MNC tries to deliver this immediately, regardless of the dial timing settings)
- **SOURCE**: The primary message source. This usually is the ID of the MNC which issued the message. Messages marked with 'USER' or 'MNC' in this column.
- **DEVICE**: The secondary message source. This gives a more detailed information about the source of the message. It may be the name of the device in a MNC which caused the event.
- **MESSAGE**: The message text.

Filter functions

Located on the right side of event report tab. All filter can be combined with each other.

- **Sort by**: The table content can sort by descending and ascending of it's time.
- **Reload button**: Reload the table content to get latest data.
- **From**: Define the start time. If you click on the calendar icon on the right-hand side, a calendar view for selecting the date is displayed. The time must be entered manually.
- **Length**: The length is a drop-down menu that allows you to select duration. If you click on the arrow button on the right or left, the hours are added (on right arrow) to or subtracted (on left arrow) from the start time.
- **To**: Define the end time. Normally this input field is disabled to activate, please select 'select end time' from length dropdown.
- **Maxlen**: Define the maximum number of events that a report may contain. There is a default value for this (1000 in most cases), which represents a good compromise between performance and the number of events displayed simultaneously. You can change this limit according to your needs, but remember: reports with millions of events can take some time.
- **MNC**: This filter lets you filter with the M&C name.
- **Device**: This filter lets you filter messages along their device (secondary source) which caused the message.
- **Host**: The host name filter lets you restrict the report to messages originated from a certain client PC. Login messages and messages logging the active change of a parameter are stored with the origin (hostname or IP4 address) of the event.
- **User**: Lets you restrict the report to messages originated by a certain user. Login messages and messages logging the active change of a parameter are stored with the name of the user who is responsible for this event.
- **Priority**: The priority selector defines the priority (or type) that an event must have in order to be listed in the report. The selection *ALL* shows all events. *FAULT* contains events that have at least fault priority. *ALARM* only shows alarm messages (see the description

of alarm priorities above). The NOT ACK selection shows all messages that (still) need to be acknowledged.
- **Text**: Filter with the message text.
- **Acknowledge all faults**: Acknowledge all faults marked with the red exclamation mark.
- **Acknowledge fault**: This button may appear if you want to acknowledge messages marked with the red exclamation mark. Simply select the row with red exclamation mark with mouse click. The exclamation mark will then disappear and a confirmation message will be added at the end of the log.
- **Export as CSV**: This button downloads the current event report, as displayed in the table, as a CSV file.

2.23.4 Active alarms

The Active alarms tab lists all actually pending faults and warnings in the M&C. The Table automatically updates its content as the faults appear or disappear.

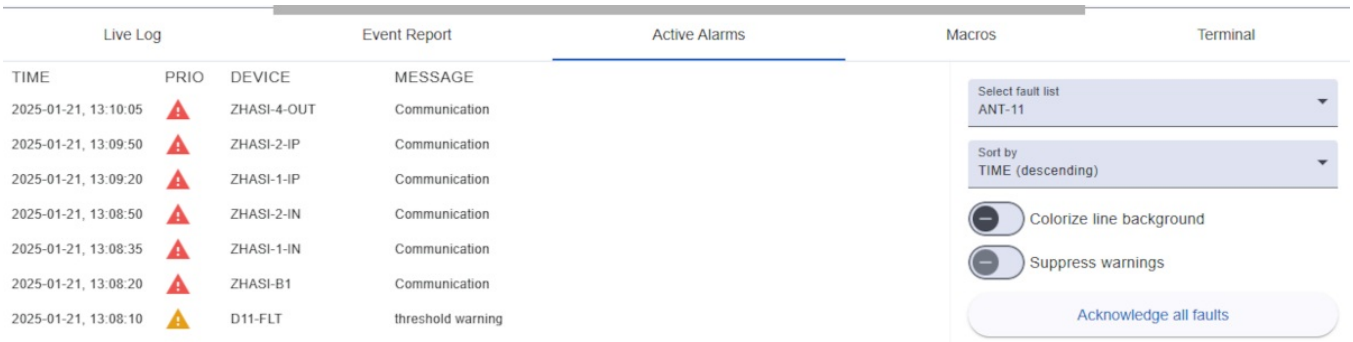

Table columns

- **TIME**: The time stamp when the event was originated
- **PRIO**: The message priority. The message priority decides on the urgency, the message gets delivered from the M&C to the client. It also is a search criteria in the Event Report window. The following priority symbols may appear:
  - : This is an informational message (lowest priority)
  - : This is a fault message (medium priority)
  - : This is an alarm message (highest priority, the MNC tries to deliver this immediately, regardless of the dial timing settings)
- **DEVICE**: The secondary message source. This gives a more detailed information about the source of the message. It may be the name of the device in a MNC which caused the event.
- **MESSAGE**: The message text.

Right toolbar

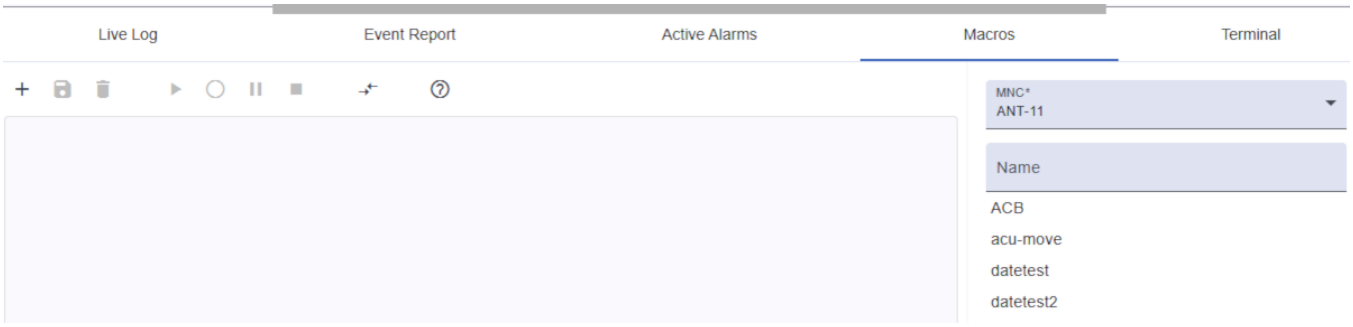
The toolbar buttons of the window let you select how the fault list displays the active faults:

- **Select fault list**: Select an MNC name from the drop-down list for which you want to check faults. Primary M&C is selected as default.

- **Sort by**: The table content can sort by descending and ascending of it's time.
- **Colorized the background**: If checked, the background of each line gets background color as the icon red for faults, yellow for warnings.
- **Suppress warnings**: If checked, the table content suppresses all warnings and show only faults only. Otherwise faults and warnings are displayed.
- **Acknowledge all faults**: Acknowledge all faults marked with the red exclamation mark.

2.23.5 Macros

The sat-nms software includes a powerful macro recording and playback feature which lets you automate complex equipment settings to one mouse click. The following chapters describe the user interface which give access to this feature.



Top toolbar

You must select an M&C from the right side toolbar, so that this toolbar can be displayed.

- **Add macro**: On click on + button you can create the new macro.
- **Save macro**: If you made some modifications you can save by clicking on this button.
- **Delete macro**: Selected macro can be deleted.
- **Play macro**: Play the selected macro.
- **Record macro**: You can start recording the macro. On toolbar of app the record icon will be displayed.
- **Pause/resume recording**: You can pause or resume recording.
- **Stop recording**: Stop the macro recording.
- **Compare macros**: To compare macros, please select macros from the macro list on the right-hand side. Both macros are displayed next to each other. The “Compare” button is displayed at the bottom of the window. It triggers a dialog that displays a better comparison. Clicking again on button will disable compare mode.

Right side toolbar

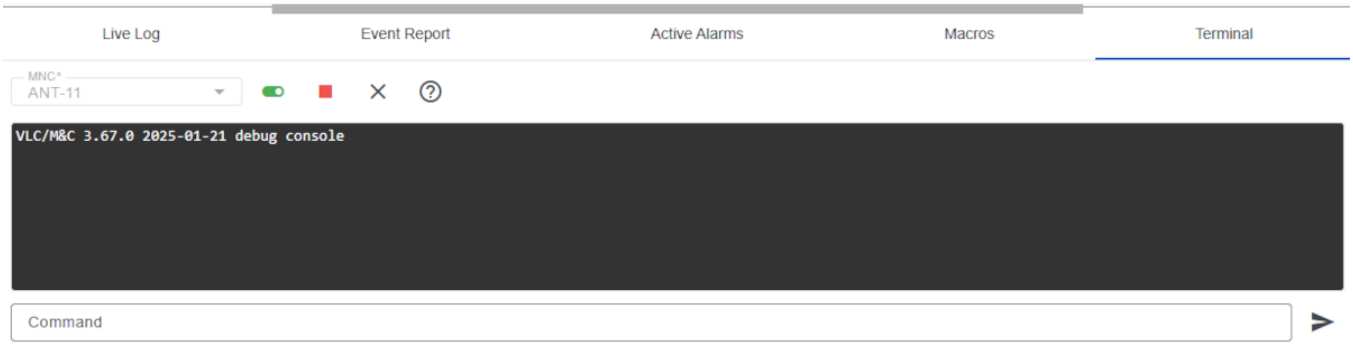
- **MNC**: Select an M&C to load all stored macros or perform other actions.
- **Name**: On creating new macro name should be entered, otherwise it works as a filter also. You can type the name of the macro to find the saved macro.
- **Macro list**: Once you selected an M&C, a macro list will be displayed under the name field. Simply select macro to perform actions described in above toolbar section.

Editing area: The macro editing area is located under the top toolbar. You can also edit the

saved macro by simply typing as you would in a text editor. This area is also used to compare macros.

2.23.6 Terminal

The terminal tab gives you access to the debug console of a M&C system. This is a valuable tool to inspect the low level communication to devices which are controlled by the M&C.



The terminal window consists of a display area which shows the debug output of the M&C and a command entry field at the bottom of the window. The tool bar at the top gives you access to the following functions:

1. **MNC**: Select an M&C to which you want to start the terminal connection.
2. **Switch**: After selecting an M&C you have to toggle this switch to start connect or disconnect the terminal connection. Green means terminal is connected.
3. **Stop/play icon**: It pauses or resumes the terminal session.
4. **Close icon**: It's clear the terminal display area.

After the terminal display area there are 'Command' input and 'send' icon. You can just type in command input and press 'enter' key to send command.

Debug commands

At the entry line at the bottom of the window you can enter a number of debugging commands which may help to test e.g. new device drivers. The following commands may be entered:

- get <msg-id> --- Get the current value of an parameter with the ID <msg-id>
- set <msg-id> <v> --- Set parameter with the ID <msg-id> to a value as it would entered by the user
- loop <msg-id> <v> --- Set parameter with the ID <msg-id> to a value as it would read from the device
- touch <msg-id> --- Force the parameter with <msg-id> to be read from the device with the next driver cycle
- threads --- Show a comprehensive list of device threads
- thread <n> --- Show details of thread number <n>
- peers --- Show peers / list of connected clients
- peer <n> (view|verbose|silent|kill) --- Details and functions of peer number <n>
- restart --- Restart MNC service (same as restart button in client)
- shutdown --- Stops MNC service. Attention: service has to be restarted on the command

line

- limit / nolimit --- make the 'debug.log' file unlimited or limited in size. The MNC always starts with the 'debug.log' file limited in size.
- csm-debug --- toggles the debug output of**all** CSM spectrum analyzers ON/OFF. The debug output appears in the `.panic.log` file. Remarks:
  - Be careful to switch csm-debug off again after using it. It remains on when the debug terminal window is closed unless it has been switched off before. This may cause a large amount data in the `.panic.log` file.
  - Using csm-debug only gives meaningful information if there is only one spectrum analyzer running in the system. If you have multiple spectrum analyzers configured, be sure to set all but the one you want to debug to OUT-OF-SERVICE.

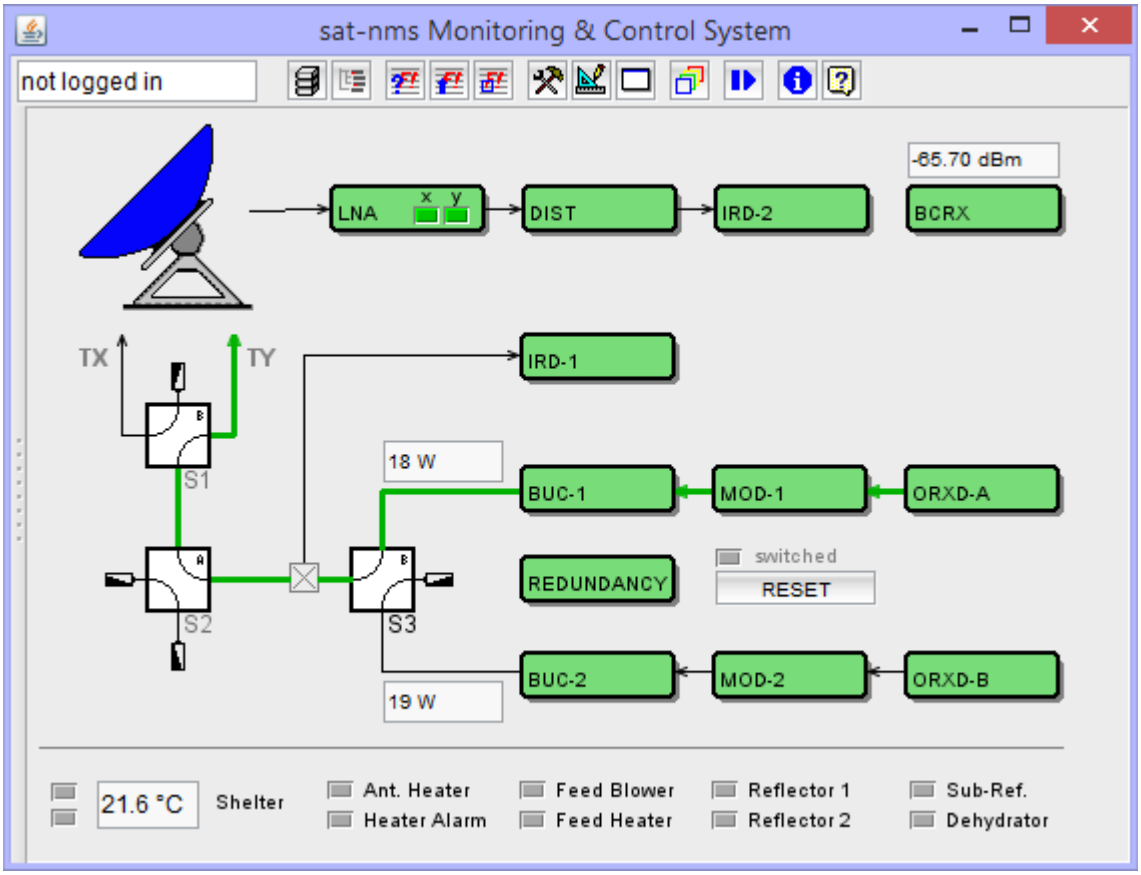
3 Legacy Java Client Operation

This section describes the functionality and the usage of the sat-nms M&C software when operated with the legacy Java client. The following chapters of the manual describe each function and each user interface screen in detail.

The satnms Java client is a legacy user interface to the software, it has been replaced by the newer Web based client. The documentation for the Java client is still provided for older M&C installations of if an installation explicitly uses the legacy client for some reason.

3.1 The M&C Main Window

The M&C main window forms the main entry point to the M&C user interface. As most of the subsidiary M&C windows, it is widely user configurable. In many cases the M&C main window will contain a block diagram showing the state of the devices operated by the M&C like shown in the example below.



In this block diagram each piece of equipment controlled by the M&C is represented by an icon in the window. The color (and/or shape) of the icons signals the state of each device. A double click to a icon opens the Device window for this device, a unified M&C user interface to it.

Tool-bar Functions

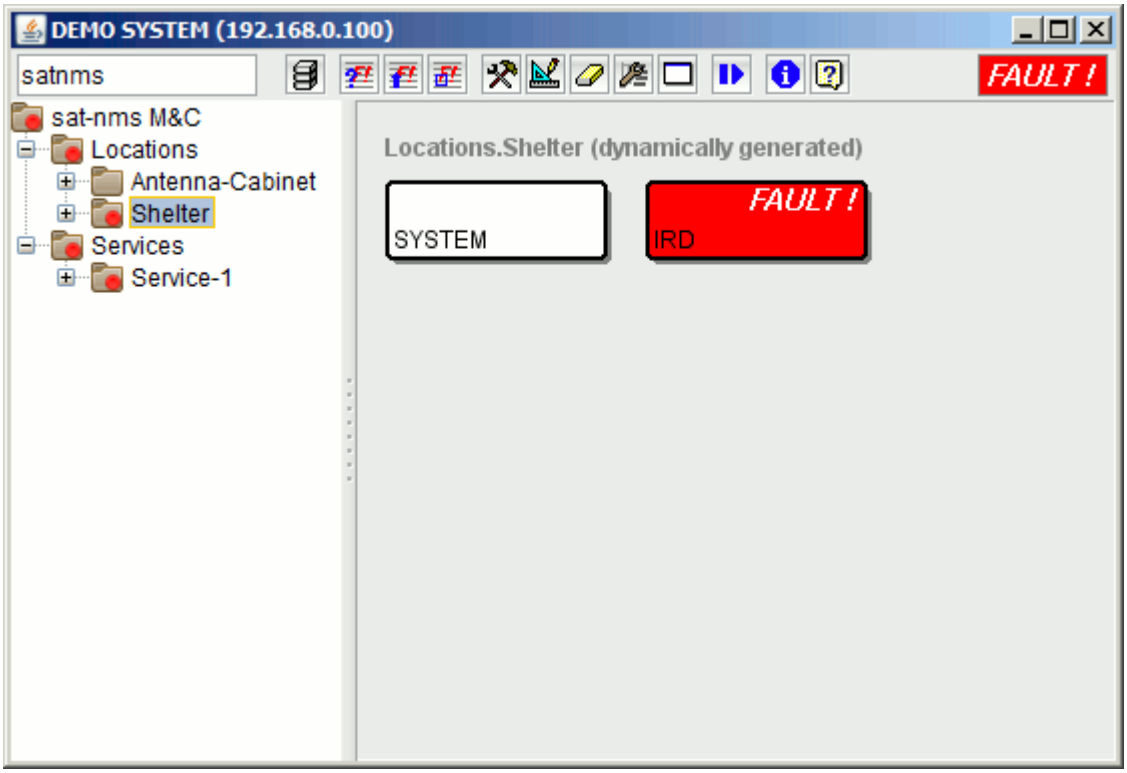
- --- The left field at the window's tool-bar shows the login-name of the user who is actually logged in. You may click with the mouse to this field, the program pops up the login/logout dialog.
- --- Shows a drop down list with all devices installed in the M&C system. Selecting a device from this list opens it's Device window .
- --- Opens the M&C Tree View Window .
- --- Opens the Event Report window .
- --- Opens the Live Event Log window .
- --- Opens a list of currently active faults.
- --- Opens the Device Setup window to configure the device setup of the M&C system.
- --- Opens the Screen Editor window to modify the layout of this M&C window.
- --- Opens a terminal window which connects to the debug / test port of the M&C server.
- --- Opens the User Management Window . You must be logged in with privilege level 150 or higher in order to open this window.
- --- Opens a file select dialog which loads or saves the window layout of the application.
- --- Opens the Macro Management window which controls recording and replay of equipment setting macros.

Remarks

- Touching a device icon with the right mouse button opens a context menu offering frequently used functions.
- As this window is widely user configurable, a particular M&C main window need not to look like the example shows here.
- Devices may be symbolized by other icons than shown here.

3.2 The M&C Tree View Window

The M&C Tree View Window is much like the M&C Main Window. It provides the same functions as the latter and adds a tree navigation bar at the left side of the window. M&C Tree View Window may used as a stand alone client window or launched from the M&C Main Window.



By default, the right side of the window shows the default user screen. The left part of the window shows the tree of subsystems and the devices attached to them. Each device node is marked with its fault state (no mark=OK, yellow mark=WARNING, red mark=FAULT). Subsystem nodes also show fault marks, summed up from the devices and subsystems contained in it.

Clicking on a node of the tree in the left part of the window changes the contents of the right part:

- If the node stands for a device, the device screen for this particular device is opened and embedded into the right part of the window.
- If the node stands for a subsystem, the right part of the window becomes a user screen, individually defined for this subsystem. This screen may be edited in the sat-nms GUI editor. If no such screen exists, the software dynamically creates screen containing all devices attached to this node in a grid.

The Tree View Editor may be used to edit the subsystem tree and the devices attached to each node.

Tool-bar Functions

- --- The left field at the window's tool-bar shows the login-name of the user who is actually logged in. You may click with the mouse to this field, the program pops up the login/logout dialog.
- --- Shows a drop down list with all devices installed in the M&C system. Selecting a device from this list opens it's Device window .

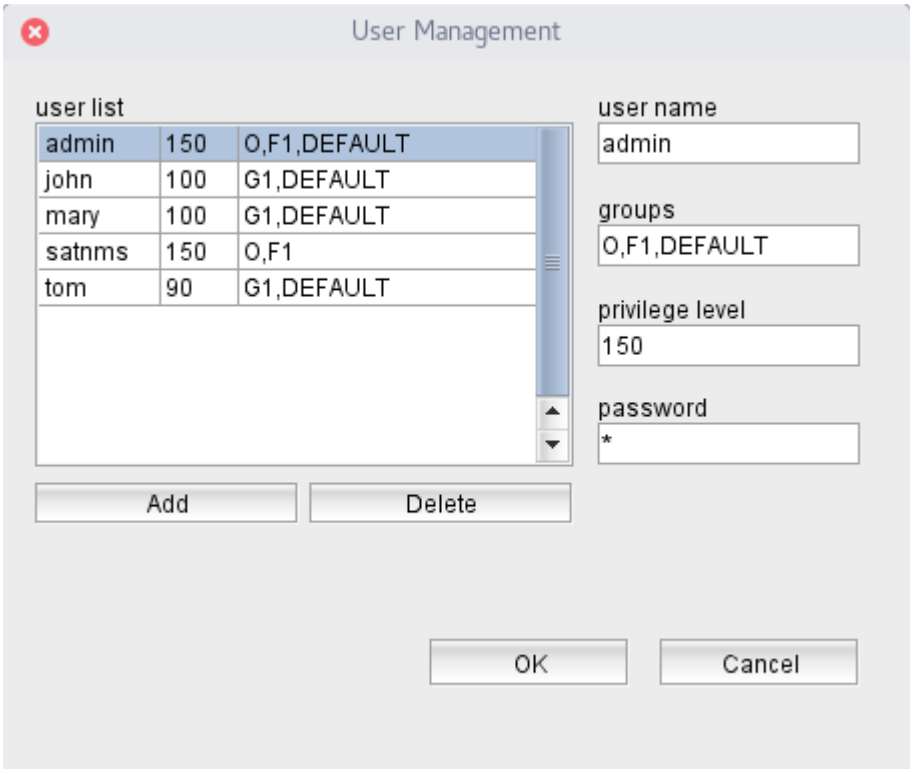
- --- Opens the Event Report window .
- --- Opens the Live Event Log window .
- --- Opens the Device Setup window to configure the device setup of the M&C system.
- --- Opens the Screen Editor window to modify the layout of the actually displayed user screen. If the screen is dynamically generated, it will be stored at the server's disc and will no longer be updated automatically.
- --- Deletes the user screen actually shown. This reverts the screen to the dynamically generated version provided by the software.
- --- Opens the Tree View Editor .
- --- Opens a terminal window which connects to the debug / test port of the M&C server.
- --- Opens the User Management Window . You must be logged in with privilege level 150 or higher in order to open this window.
- --- Opens the Macro Management window which controls recording and replay of equipment setting macros.

Remarks

Tree nodes may be expanded or collapsed either by clicking to the '+' marks in between the nodes or by double-clicking the node to expand/collapse.

3.3 The User Management Window

The user management window lets you manage the list of users which are allowed to operate the software. You need to be a "super user" with privilege level 150 or higher to open the user management window.



The user management window shows a list of all users known to the software. You may click to a user in the list to show the properties of this user in the entry fields right of the list.

- *user name:* The login name of the user. You cannot change the name of an existing user because this name identifies the user in the sat-nms software. You can however change the name in this field and press the button "Add" below the user list to create a new user definition.
- *groups:* This field takes a comma separated list of group identifiers. With the normal M&C software groups are meaningless, with the NMS software or the VioIP software however groups control which VLCs or which equipment a particular user may access. To change the group membership of the selected user simply edit/overwrite the group list and press enter.
- *privilege level:* The privilege level controls if a user may only control some basic aspects of the M&C system or if the operator may change everything. Higher numbers mean higher privileges or more comprehensive control. The privilege level numbers are often unique to the particular installation. Many installations of the sat-nms software however use the following standard levels:
  - 150 = super user, may control everything including all configuration tasks.
  - 100 = general user, may control all aspects of all devices, but may not change the sat-nms software configuration.
  - 90 = user with limited access to some devices or parameters only. Makes sense only together with a default screen wich gives no general access to all devices.To change the privilege level of a user, enter the new level value and then press enter.
- *password:* This field always displays a single asterisk, even as a super user you cannot see a user's password. You can however set a new password for the user simply by typing in into tge entry field and pressing enter.

To add a new user to the list, type the name of the user in the "user name" field and click the "Add" button. This takes the actually selected user as a template and creates a new user with the group memberships and privilege level of the template. The new user has no valid password set, you have to set an initial password for the new user explicitly by typing it into the "password" field. The user may change this password later.

To delete a user from the list, select the user to delete and click the "Delete" button below the user list.

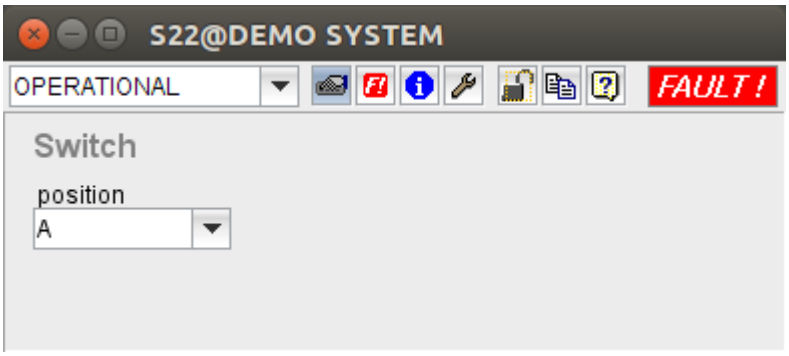
The software does not change the user database until you leave the user management window with the OK button. By pressing "Cancel" you can abort the edit process at any time.

Changed user permissions and credentials are valid with the next login of the user. Users currently remain with their privilege level and group assignments they had at the time they logged into the sat-nms software.

3.4 The Device Windows

The software offers a Device window for each type of equipment it supports. Device windows are launched by double clicking to the device icons in a M&C user interface window . It shows all parameters read from the device and permits to alter each writable parameter. For

clearance, the parameters are grouped to pages, you can switch between the pages using the tool-bar.



Writable parameters are shown with a light gray background, read only parameters appear with the standard gray background of the window. Choice parameters are changed immediately when you alter the selection. If you edit a text parameter, the field is shown with a yellow background. Once you press ENTER or you leave the field, the changed value gets transferred to the device. To cancel a parameter setting press ESC. The old value gets restored in the field and the background color returns to light gray. No parameter value is sent to the device in this case.

Tool-bar Functions

- --- The operation mode selector displays and sets the device operation mode. Device operation modes are:
  - **OPERATIONAL** --- This is the normal operation mode.
  - **FAULT-SUPPRESSED** --- The M&C server normally polls and controls the device, but does not generate a device summary fault if the is a fault condition with this unit.
  - **OUT-OF-SERVICE** --- The M&C server does not try to communicate with the device at all. If you alter parameters of a device in this mode, this has no effect.
- --- Opens a Load Device Preset dialog which lets you select a formerly stored device preset and apply the stored setting to the device. The chapter ' Managing Device Presets ' gives more information about device presets and how to handle them.
- --- Opens a Store Device Preset dialog which lets you store the actual device settings at the server for later retrieval.
- --- Switches the window to the 'faults' page. This page displays all fault flags the software knows about this device. Moreover, you can view and change the event priority for each particular fault flag:
  - Click to a fault flag and hold the mouse button down to see the event priority actually set.
  - Use the context menu (right mouse button) to change the event priority.

Valid selections for the event priority are:

- **OFF** --- This flag is completely suppressed.
- **INFO** --- This flag is signaled as an 'informational' event.
- **WARNING** --- This flag is signaled as a 'warning' event.
- **FAULT** --- This flag is signaled as a 'fault' event.
- **ALARM** --- This flag is signaled as an 'alarm' event.
- --- Switches the window to the 'info' page. This page gives some information about the type of equipment controlled.
- --- Switches the window to the 'maintenance' page. This page lets you set some configuration parameters and gives access to the 'low level interface' of the device.
- --- Locks the operation of the device that no other user can change device settings. See paragraph device locking below for details. If locked, the button shows a closed red lock:
- --- Duplicates / clones this window. This is useful if you want to have more than one instance of a device window open at a time.
- --- Launches the web browser with the help page for this individual device type. For a list of device types supported by the software see the 'Device Driver Reference' .

Device locking

Clicking the button once locks the operation of the device. The button icon changes to . If the device is locked, no other user may change devices settings. Locking is done along the user name, hence if you are logged in a second time an another place, you can operate the device from there as well.

A second click to the lock button releases the lock. Only the operator who set the lock may release it. This need not to be done at the same place where the lock was set bot you must be logged in with the same user name.

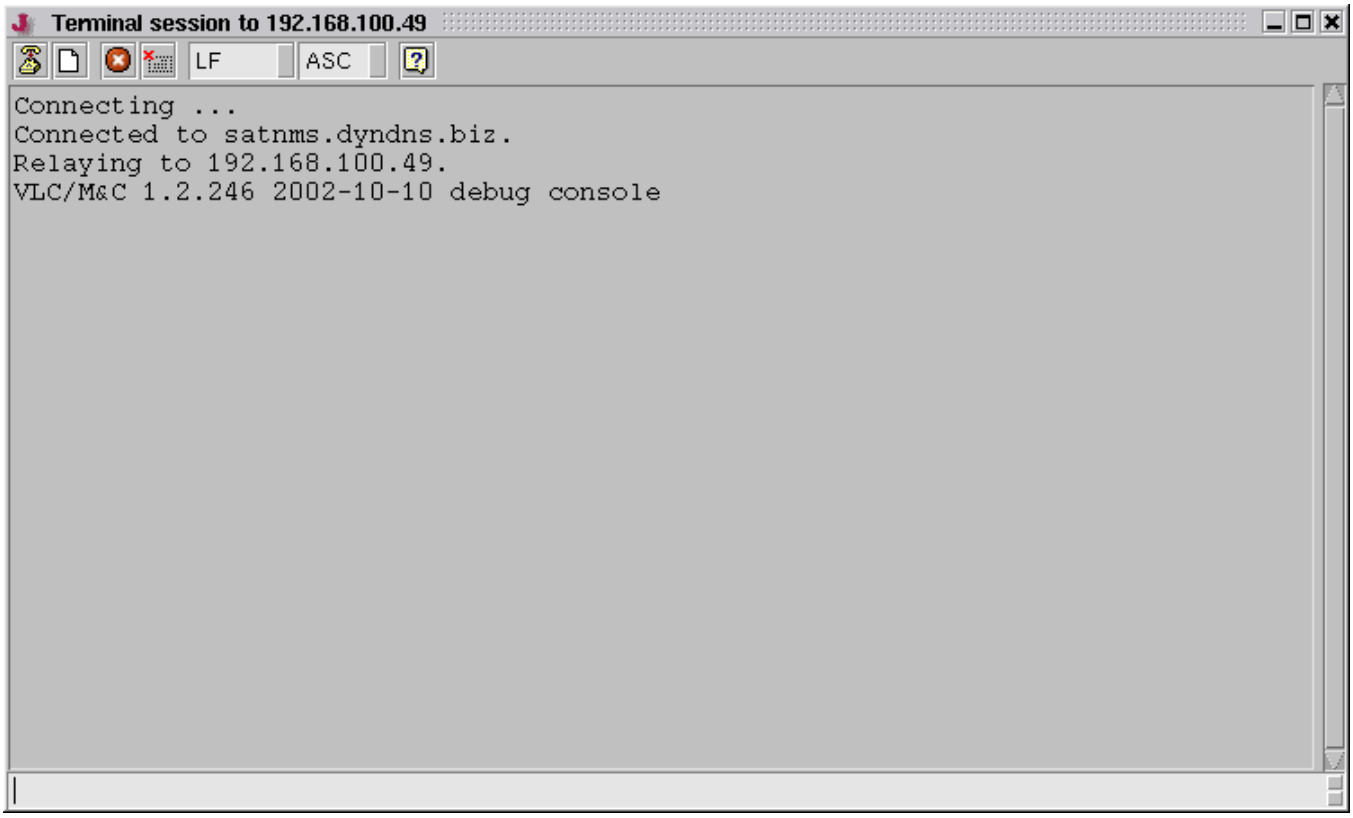
Administrators (with a privilege level of 150 or above) may release the lock in any case, also a restart of the sat-nms M&C server releases all pending device locks.

Remarks

- Units and unit factors displayed with a parameter are for information only. They are ignored when you enter a new value. Hence you cannot enter a value expecting 'MHz' in GHz by changing the unit multiplier.

3.5 The Terminal Window

The terminal window gives you access to the debug console of a VLC or M&C system. This is a valuable tool to inspect the low level communication to devices which are controlled by the M&C.



The terminal window consists of a display area which shows the debug output of the VLC and a command entry field at the bottom of the window. The tool bar at the top gives you access to the following functions:

- --- Disconnects from the VLC / M&C and closes the window (same as the 'q' command).
- --- Clears the window.
- --- Temporarily inhibits the output of data sent by the VLC / M&C.
- --- closes a 'term' connection to a certain serial interface.
- LF --- Selects the 'end of line' terminator appended to each commands entered to the command field at the bottom of the window. Possible selections are LF, CR, CR/LF, and ---.te .ts ASC Selects ASC or HEX mode. ASC is the normal terminal mode displaying printable characters as they are. HEX is the HEX-dump mode displaying each character as a 2-digit hexadecimal number. The mode affects the command entry, too.

Debug commands

At the entry line at the bottom of the window you can enter a number of debugging commands which may help to test e.g. new device drivers. The following commands may be entered:

- get <msg-id> --- Get the current value of an parameter with the ID <msg-id>
- set <msg-id> <v> --- Set parameter with the ID <msg-id> to a value as it would entered

by the user
- loop <msg-id> <v> --- Set parameter with the ID <msg-id> to a value as it would read from the device
- touch <msg-id> --- Force the parameter with <msg-id> to be read from the device with the next driver cycle
- threads --- Show a comprehensive list of device threads
- thread <n> --- Show details of thread number <n>
- peers --- Show peers / list of connected clients
- peer <n> (view|verbose|silent|kill) --- Details and functions of peer number <n>
- restart --- Restart MNC service (same as restart button in client)
- shutdown --- Stops MNC service. Attention: service has to be restarted on the command line
- limit / nolimit --- make the 'debug.log' file unlimited or limited in size. The MNC always starts with the 'debug.log' file limited in size.
- csm-debug --- toggles the debug output of**all** CSM spectrum analyzers ON/OFF. The debug output appears in the `.panic.log` file. Remarks:
  - Be careful to switch csm-debug off again after using it. It remains on when the debug terminal window is closed unless it has been switched off before. This may cause a large amount data in the `.panic.log` file.
  - Using csm-debug only gives meaningful information if there is only one spectrum analyzer running in the system. If you have multiple spectrum analyzers configured, be sure to set all but the one you want to debug to OUT-OF-SERVICE.

3.6 The History File Viewer

The sat-nms M&C software provides a facility (a logical device) calledFile-Recorder which is capable to record arbitrary data like levels, antenna pointing etc. into a disc file. The *History File Viewer* is the user interface to inspect such files. The window can be accessed either from the File-Recorder's device window or can be used as a stand alone application as well (see below for details).

The window shows a diagram of the recorded data, the fields and buttons in the tool bar permit to modify the appearance of the diagram as needed. Clicking into the diagram shows a marker which displays a readout of the value at the selected screen position.

Top Toolbar

- --- Loads a file from a local disc. Opens a standard file select dialog. You may use this to display files you have archived on you local PC.
- --- Gets a file directly from a remote sat-nms M&C. When you started the*History File Viewer* from within the sat-nms GUI, it usually will already display the data you want to see on startup. If you started the file viewer as a stand alone application, you use this function to connect to a M&C system and get the data from there.
- --- Saves / archives the recorded data as a disc file to the local computer. A file select dialog is shown where you can select or enter the name of the file to save. The file format is text based, saved files can be re-opened with the open icon in the tool bar. The textual format of the file also permits to process the saved data with a spreadsheet program or with gnuplot.
- --- Moves the plot two divisions to the left, lets you see older data.
- --- Moves the plot two divisions to the right, lets you see younger data.
- --- Shows/edits the start time. The displayed time corresponds to the leftmost grid line in the diagram. You set the start time by changing the value with the keyboard and then pressing ENTER or you may double-click to the field which displays a small calendar window which lets you select a another date in a comfortable way. When you change the start time, you should consider, that the software always aligns the value that in fits into the grid of the time scale. This means if e.g. the time scale is 1 hour/div, a start time

entered gets always aligned to a full hour.

- --- Zooms in the time scale, shows a smaller section of the data more detailed.
- --- Zooms out the time scale, shows a larger section of the data.
- --- Zooms out to show the entire plot. Please note, that the largest available scale shows 720 days (30d/div). If the data you are displaying covers a larger time span, you will not see the complete data even after zooming out fully.
- --- toggles live view / normal mode (see paragraph "Live view mode" below for details).
- --- Opens the trace properties dialog window (see below for details).
- --- Prints the diagram as actually shown.
- --- Shows this manual page.

Bottom Toolbars

Below the diagram, the History File Viewer provides four toolbars to modify the scaling of the up to four traces shown in the diagram.

- --- The first control in each toolbar selects if the trace shall be drawn.
- --- Shows the color if this trace, clicking to the color fields opens a dialog which lets you change the color of the trace.
- --- Shows the name / description of the trace. When called directly from the File-Recorder device screen, the History File Viewer shows the IDs of the recorded parameters here, "Trace n" if the trace name is not known. Trace names may be set by the operator and saved on the M&C server, see the paragraph about adapting the diagram properties below.
- --- Moves the trace upwards one division.
- --- Moves the trace down one division
- --- Shows the y-scale reference level and the actual scaling. The y-reference level is the value corresponding to middle grid line.
- --- Zooms in the y-scale for this trace.
- --- Zooms out the y-scale for this trace.
- --- Zooms to show the min/max values (autoscale). This refers to the entire data, not only to the part actually shown.

Getting data directly from a M&C system

The history file viewer is capable to get the data to tisplay directly from a remote sat-nms M&C system. This feature can be used also if the viewer has been started as a stand alone application.

Clicking to the button in the tool bar opens the remote load dialog window. In this window, enter the IP address of the M&C computer you want to read from and click to the button right beside the entry field.

- 
--- The selection list field now shows 'connecting ...' and after a couple of the seconds, the files which look like File-Recorder data files are displayed in the the selection box. Select the file (the name of the File-Recorder logical device) you want to load an click to 'OK'.The histoy file viewer in this case loads *both* files belonging to the File-Recorder device if they are available. If you load the data from a File-Recorder named FREC1, the file viewer tries to get the files FREC.old.txt and FREC.txt and concatenates them in memory.

If the file recorder is not able to read from the remote M&C system, the 'connecting ...' notice remains visible permanently. In this case verify the IP address you entered, close the window and try again.

Live view mode

Beside for viewing stored log files, the *History File Viewer* can be used to display the logged data as it is acquired with an automated display update. By pressing the "live view" toggle button in the toolbar, the viewer changes to live view mode. In this mode the viewer shows up to 400 recent data points, automatically updated with an interval that is configurable separately from the standard interval at the File-Recorder device setup page.

Due to the automatic display update, the viewer and its autoscale functions behave slightly different in live view mode:

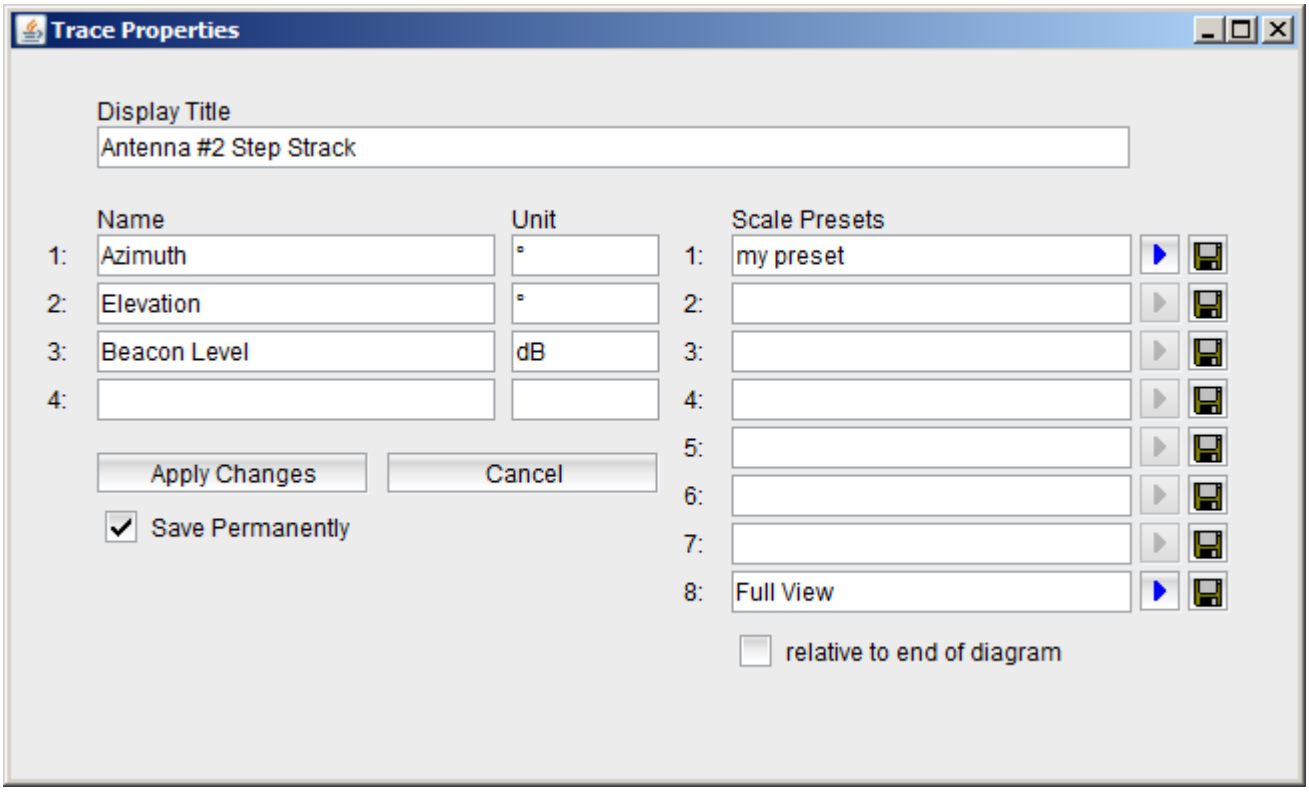
- The diagram gets aligned with the right edge of the frame with time axis autoscale and every time the display gets updated with new data points.
- When switching to live view mode, the time scale is adjusted once to show the entire (up to 400) live view data points.
- You may change the time axis scaling to your need with the zoom in/out buttons in the upper toolbar, the viewer won't overwrite this when the display gets updated.
- You also may change the time axis start value with the blue arrow buttons in the upper toolbar, but the viewer will revert this when the display gets updated.
- You cannot zoom or scroll outside the limited range of data points used for live view

mode. To view older data, switch back to normal mode.
- Loading or saving disc files is not possible in live view mode. If you try, a message is displayed and the viewer remains in live view mode.
- On the other hand, live view mode is not possible if the viewer shows the contents of a local file instead of the data from a File-Recorder device on a M&C.

To leave live view mode, click the "live view" toolbar button again. The viewer re-reads the full history data and performs an autoscale.

Adapting the diagram properties

The in the tool bar opens the trace properties dialog window. This dialog lets you set the name of each trace, the unit which shall be displayed with the scaling information fo each trace and a diagram title. The latter is shown in the diagram window title bar and also above the plot in the printout.



If you select the 'save' option, the trace properties are written to file named like the data file, but with the suffix '.frv'. The file is written to the same place where the data file was loaded from. When you load this data file the next time, the saved trace properties are used automatically.

The Trace Properties dialog also lets you save and recall up to 8 scaling presets. These presets may help you recall certain settings of y/t scaling.

- --- Stores the name of the preset, the color of each trace, if the trace shall be drawn or not and the actual scale settings to the given preset memory. The presets are stored together with the trace names in the '.frv' file on the M&C server.

- --- Recalls this preset, restores the trace color, the trace enable state and the scale settings from the stored values. If the preset wasn't set before, the preset recall button is inactive.

If you check the mark below the preset list before recalling a preset, the start time of the diagram is set relative to diagram end. This means, the start time stored in the preset is ignored, the start time is set to show the recent data in the diagram.

Zooming to the cursor position

When you zoom the time axis of the diagram using the ool bar buttons, the viewer tries to keep the start time of the diagram constant. If you want to have a more detailled look on a certain event, the event you want to zoom to will probably move out tof the visible part of the display. To zoom to certain position on the time axis, hold down the SHIFT key and click to the position you want to zoom to. Holding the CTRL key while clicking works the other way round, the plot gets zoomed out.

Starting the viewer as a stand alone application

Assuming your sat-nms client software is installed at 'c:\satnms', the command line to start the history viewer is for a windows based computer:

java -cp client.jar satnms3.gui.FiledRecordFrame

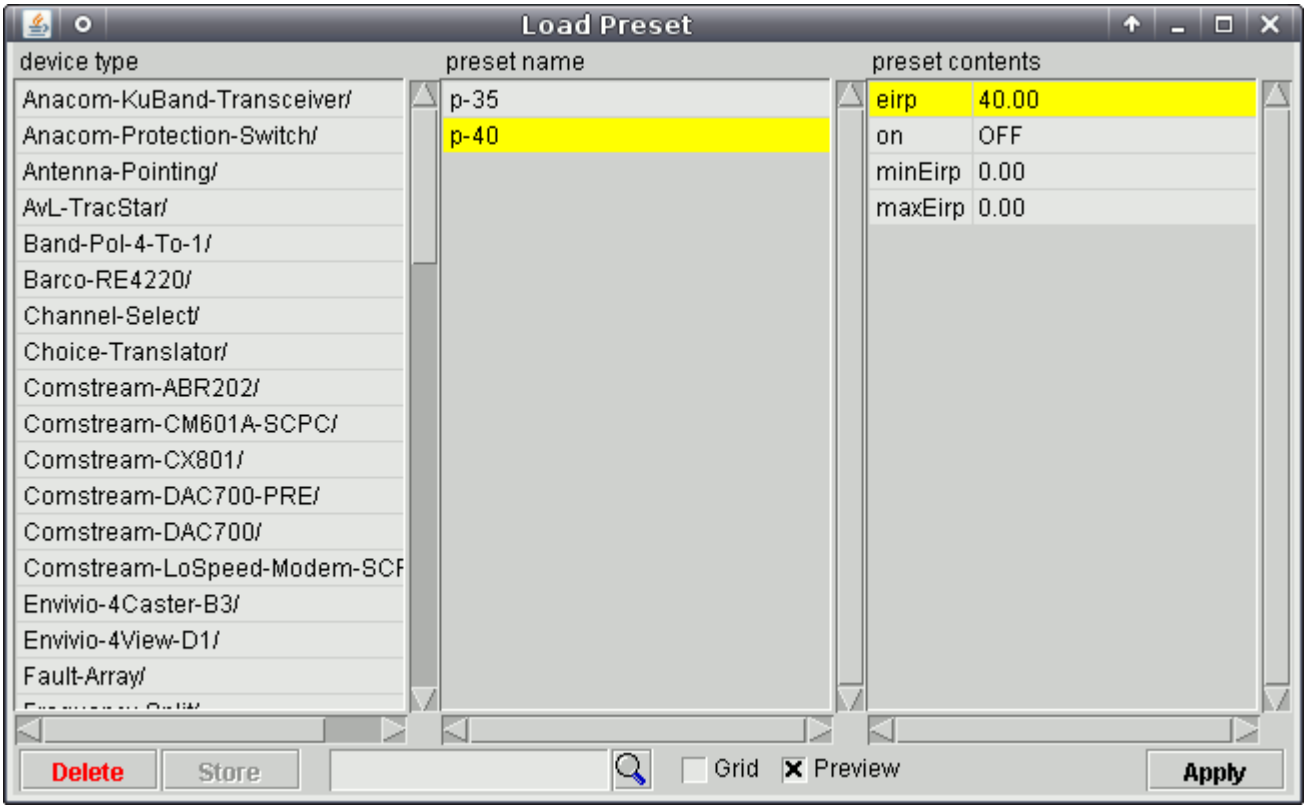
You may add this command as a start menu entry or as a desktop icon to your working environment.

3.7 Managing Device Presets

Most of the sat-nms device drivers allow to store a snapshot of the device's settings in 'device preset' files and let the operator restore these settings at a later time. The load / store preset feature is accessible though the tool bar of the device's ' Device Window '.

Presets are stored at the server your client program connects to. In a M&C environment this is the M&C server, with a NMS environment this is the central NMS server. This means in the latter case a preset may be stored while operating one VLC and later may be applied to a device on another VLC.

Presets always are dedicated to the device (driver) type they were recorded with. This is because is makes no sense to apply the settings of a beacon receiver to a DVB encoder. The target device will not 'know' what to do with the receiver settings. Even with similar devices (e.g. two IRDs from different vendors) there may be differences between the number and type of settings the devices understand. Hence, the software stores the preset files in a "by device driver" structure.



To load a stored preset, click the 'load preset' icon in the device window tool bar and select the preset in the middle list of the displayed dialog. If the *Preview* mark at the bottom of the dialog is checked, the right column shows the selected preset's contents. You may want to uncheck the *Preview* mark if your your connection to the M&C/NMS Server has a very poor bandwidth. Press *Apply* to apply the settings stored in the preset and close the dialog.

If there is a huge number of presets defined for the actual device type, the search function helps to find the proper preset file: Enter a search key into the field at the dialog's bottom line and press the search button to display only presets which contain the key in their name (the search is not case sensitive). You may specify multiple keys, separated by space characters. Only presets which contain *all* of the keys in their name will appear in the list.

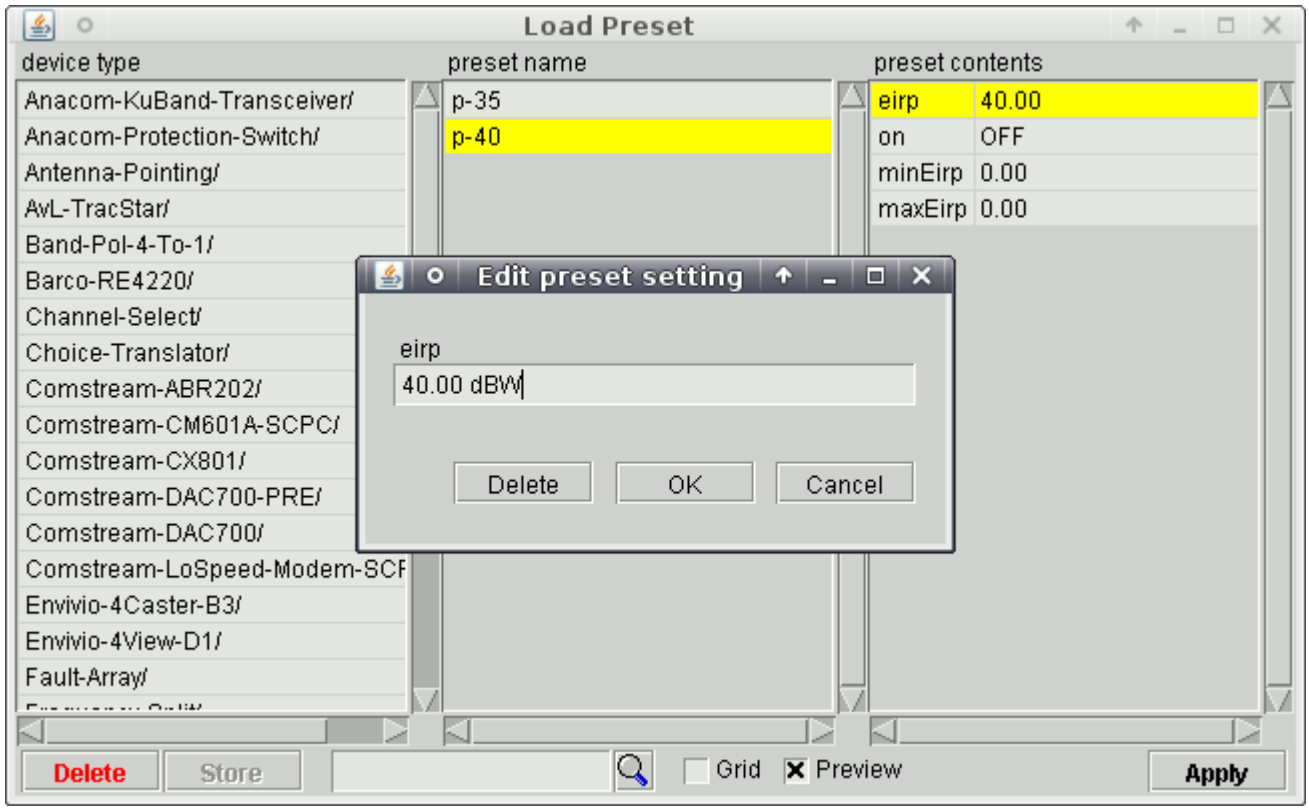
You may align the list of preset names to columns along the dashes in the names by checking the *Grid* mark. This specially is useful, if you strictly follow a certain naming scheme for your presets (e.g. something like 'satellite-channel-variant').

As mentioned above, presets are dedicated to the device type used to record them. However, for special applications the preset load dialog allows to apply a preset from another device type. For this, select the device type in the left column and then the preset file in the middle column. The program displays a prompt you have to quit, to prevent you from accidentally applying a preset from a wrong device type.

Editing Presets

If your system administrator gave you the permission for this, you are able to modify stored presets. The software supports both, permanently modifying a preset definition but also

changing some parameter temporarely before applying the preset:



Be sure to have the *Preview* mark checked and select the preset to modify. Double-clicking a parameter in the right column opens a small *Edit preset setting* dialog showing the value stored for this parameter. You may change the value to your needs and quit the dialog with the *OK* button to accept the modification. Clicking *Delete* removes the selected parameter from the preset which means that this parameter remains unchanged when the preset gets applied. *Cancel* leaves the dialog without changing the parameter.

Changes made to the preset file this way are temporary, they are made in a local copy of the preset. If click to *Apply* , the modified preset gets applied to the device. To store the edited preset permanently at the server, click the *Store* button which is now activated since the preset has been modified.

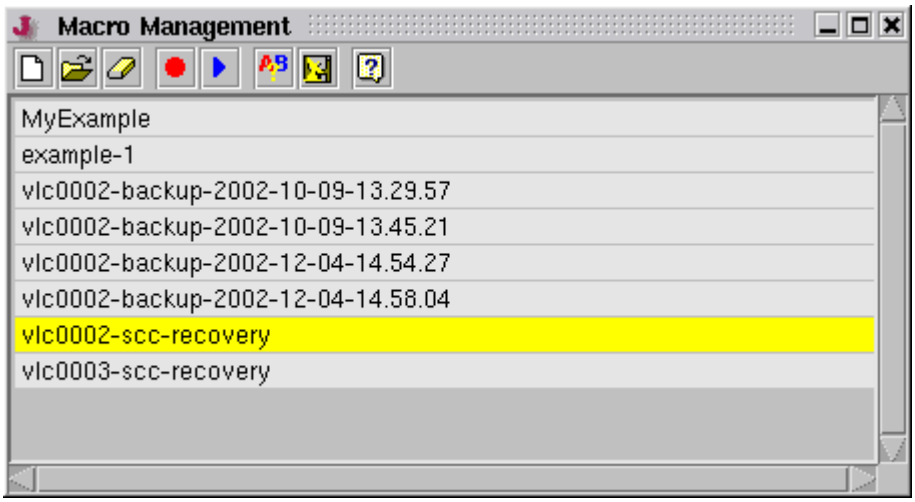
3.8 Recording and Playing Macros

The sat-nms software includes a powerful macro recording and playback feature which lets you automate complex equipment settings to one mouse click. The following chapters describe the user interface windows which give access to this feature.

3.8.1 The Macro Management window

The Macro Management window is the starting point for all operations like recording, playing, editing or deleting parameter setting macros. The window is shown if you click to the ▶ button in the tool bar of the M&C / VLC main window. To get an introduction to parameter setting

macros, see the chapter ' Concepts ' above.



The window shows a list of all macro definitions stored at the server, double clicking a list item opens the macro in the Macro Edit window . Other functions may be called using the tool bar buttons as explained below.

- --- Opens the Macro Edit window with a new, empty macro definition.
- --- Opens the selected macro in the Macro Edit window .
- --- Deletes the selected macro.
- --- Starts recording a new macro definition.
- --- Plays the selected macro.
- --- Compares the selected macro to another one. Please note the macro comparison function ignores all macro directives and does no parameter substitution. This function primary is meant to compare macros which have been recorded with the backup function contained in the SYSTEM device.
- --- Saves the selected macro as the SCC recovery macro to the actual VLC. This icon only is active if the Macro Management window has been called in the context of an SCC enabled NMS application.

Remark

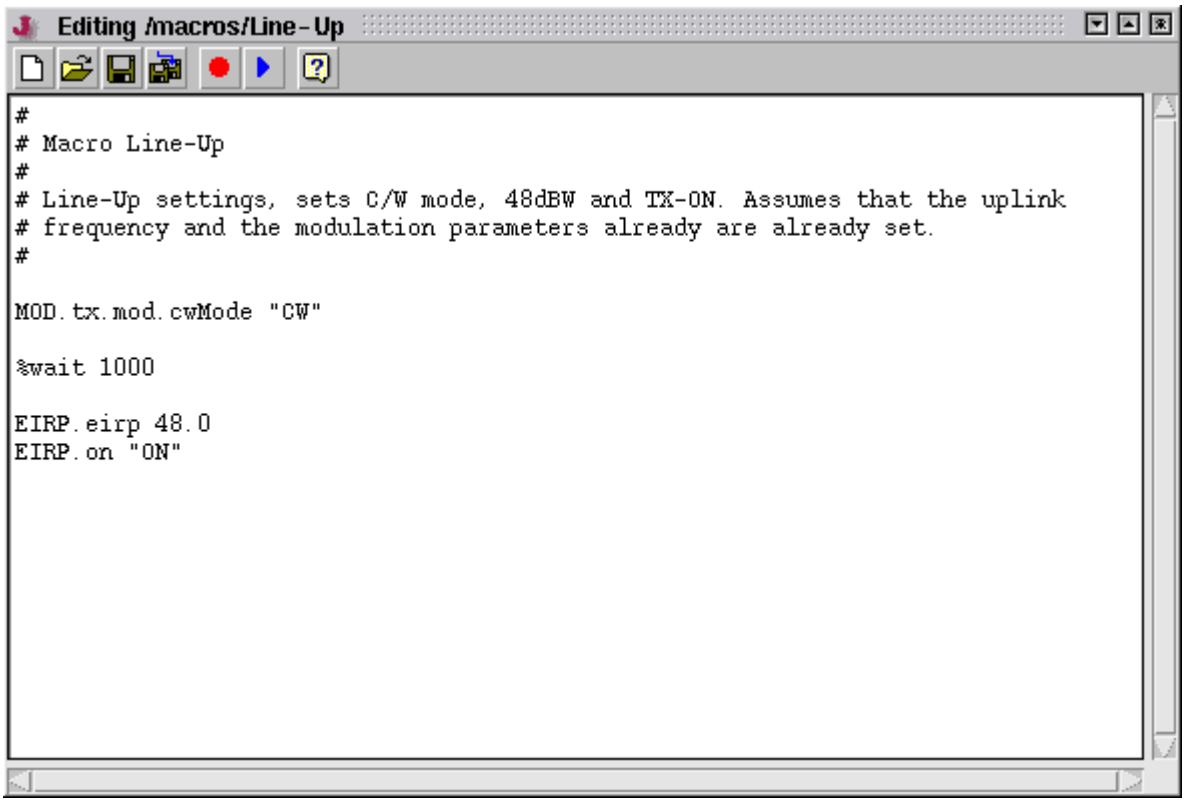
In an NMS, macros normally only can be played while the VLC this Macro Management window refers to is 'online'. An exception from this is a NMS controlling it's VLCs via SCC. Here macros also may be played for 'offline' VLCs, the commands get streamed to the SCC outbound communication channel in this case.

Macros played through the SCC outbound channel may be used to reinitialize a VLC's SCC transmit equipment if any attempts to setup a point to point connection to this VLC fail.

3.8.2 The Macro Edit window

The Macro Edit window lets you edit a macro definition (it's just a plain text file), play the edited macro or append additional steps using the record function. Before you start to edit your first macro, you might want to read the chapter ' Concepts ' at the beginning of this section

which explains the theory, file syntax and usage of these macros.



Handling the editor window (specially using cut & paste) slightly differs for Windows and Linux based computers. The window uses the cup & paste scheme of the operating system, so CTRL-C/CTRL-V works only on Windows based computers while pasting with the middle mouse button only is supported by Linux based machines. Below the tool bar functions are explained:

- --- Clears the edit buffer, lets you edit a new macro definition.
- --- Loads an existing macro definition into the editor.
- --- Saves the edited macro.
- --- Saves the macro using a different name.
- --- Starts a recording session which appends steps to the macro you're actually editing.
- --- Plays the macro in the edit buffer. The macro is played directly from memory, not saved.

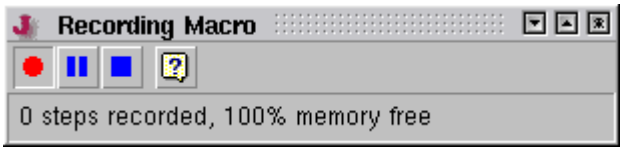
Remark

In an NMS, macros normally only can be played while the VLC this Macro Management window refers to is 'online'. An exception from this is a NMS controlling it's VLCs via SCC. Here macros also may be played for 'offline' VLCs, the commands get streamed to the SCC outbound communication channel in this case.

Macros played through the SCC outbound channel may be used to reinitialize a VLC's SCC transmit equipment if any attempts to setup a point to point connection to this VLC fail.

3.8.3 The Macro Record window

The Macro Record window lets you control the recording of a parameter setting macro. It is shown whenever a macro is recorded. Closing this window in the title bar of the window abandons the recording session, any recorded steps are lost.



The window shows the number of steps which have been recorded in the actual session and the percentage of available memory the macro actually occupies. The recording process is controlled by the tool bar buttons:

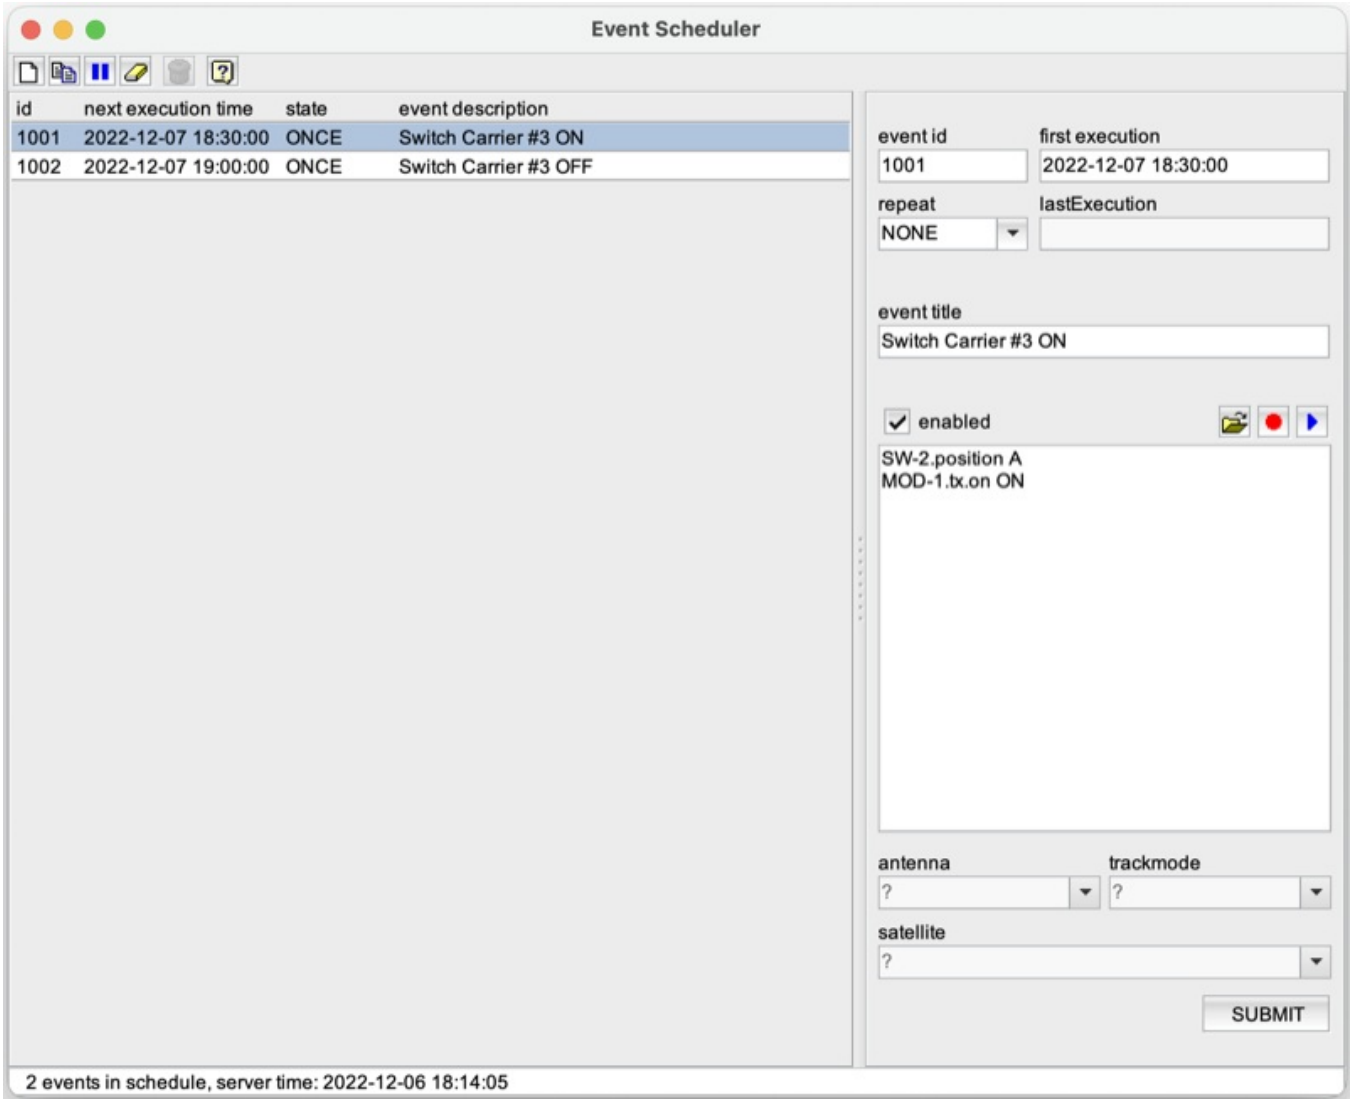
- --- If pressed down, recording is active. This is the default after the window appears. You may pause recording by pressing the pause button described below. To resume recording, click to the record button.
- --- Pauses recording. If, e.g., you find during a recording session that some device settings are not set as you expect, pause recording, set these settings and then resume recording the macro.
- --- Stops the macro recording session and loads the macro into the Macro Edit window. You may modify the macro there, add a comment and store it with an arbitrary name.

3.9 The Macro Scheduler

The macro scheduler included in the sat-nms M&C software lets you execute macros at planned times. You access the macro scheduler from the M&C main window by clicking to the toolbar icon which shows a clock icon.

The scheduler supports events which are executed once at a given time as well as repeated events on a daily, weekly or monthly base. Repeated events are executed in the planned was up to a given end date. Monthly repeated events are executed every month at the programmed day of month. If you program a monthly event for 29.-31. of a month, it will be executed at the last day of a month which is shorter.

The macro scheduler window shows a scrollable list of planned events and provides controls to add, edit or delete events. Like with the macro management window, you may either record the macro you want to be played at the event's time or enter the commands manually. It is also possible to load a stored macro into the event.



The left side of the window shows the list of scheduled events, the right side shows the properties of the actually selected event (or the properties of the new event if you are about to create a new event). Events are sorted by the time of their next execution, the event to be executed next appears on top of the list.

By default the scheduler deletes events once the last execution of this event has been done, however, the scheduler may be configured to keep these events. In the latter case, outdated events appear at the bottom of the list, grayed out with the state DONE.

The toolbar at the top of the window contains all functions to manage the schedule, to add or remove event or to toggle their enabled state:

- Clears the properties section on the right, lets you enter the properties of a new event.
- Makes a copy of the actually selected event into the properties section on the right. You may edit this copy to your needs, the edited event will be added to the schedule when you click "Submit".

- Toggles the enabled state of the actually selected event. Disabled events appear grayed out in the event list, the macro execution is suppressed for a disabled event.
- Deletes the actually selected event from the schedule.
- If the scheduler is configured to keep outdated events in the schedule and if there are such events in the schedule, this toobar button becomes active. Clicking it cleans up the schedule an deletes all outdated events.
- Shows this help page.

The section of the right side of the window contains the properties of the actually selected event of a new event you are about to create. Below a short description of all entry fields and buttons on this section:

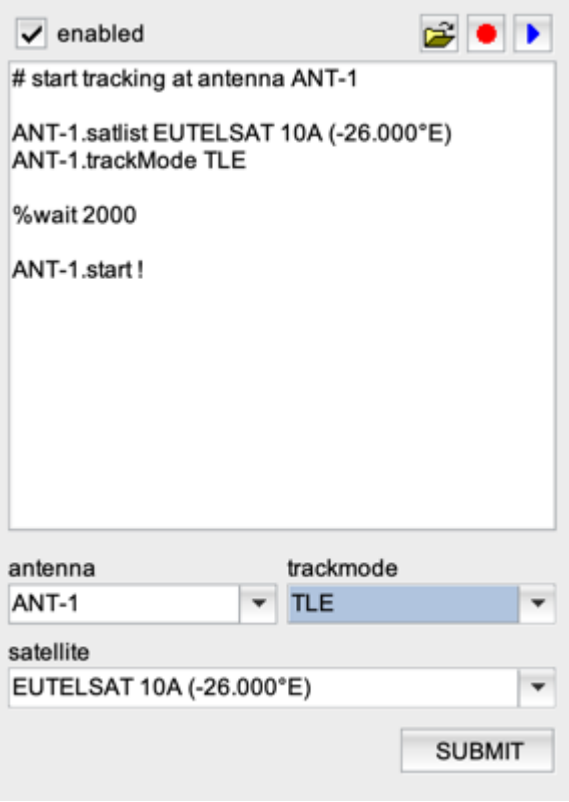
- **event id:** The event id is a unique identifier issued by he scheduler for each event. The event id cannot be changed by the operator.
- **first execution:** The date and time of the first execution of the event (for repeated events) or simply the time of execution for an event executed only once. Be sure to enter the date/time exactly in ISO format: YY-mm-dd HH:MM:SS, the program will reject entries formatted in another way. Double click into the entry field to open a pop up calendar widget which assists you entering the date.
- **repeat:** The repeat mode for the event. This may be one of:
  - **NONE:** The event is executed once at the date and time specified in "first execution".
  - **DAILY:** The event is executed first at the date and time specified in "first execution", then at all following days at the same time but not beyond the day given in "last execution" below.
  - **WEEKLY:** The event is executed first at the date and time specified in "first execution", then every seven days at the same time but not beyond the day given in "last execution" below.
  - **MONTHLY:** The event is executed first at the date and time specified in "first execution", then every month at the same day of month and time but not beyond the day given in "last execution" below. If you program a monthly event for 29.-31. of a month, it will be executed at the very last day of any month which is shorter.
- **last execution:** The day of the last execution of the event.
- **event title:** A descriptive title for the event which will appear in the event list at the left side.
- **enabled:** If checked, the event is enabled. An enabled event will execute its macro at due time, a disabled event will skip this.
- **macro text:** The large field below the "enabled" check mark contains the macro text to be executed. The format and syntax of the macro text follows exactly the definition given in section Automating Procedures With Macros . Unlike the standard macro facility of the software which stores macros as text files in a separate directory, macros of the scheduler are store with the schedule itself, they are not accessible from the software's macro player.
  - Lets you load an existing macro file into the macro for this event. The loaded file will replace the previous content of the entry field.
  - Lets you record the macro. While recording is active, all parameter settings you make at the GUI are recorded an added to the macro.

- ▶ By clicking this button, you can immediately execute the edited or recorded macro for testing.

- **SUBMIT:** Clicking SUBMIT actually adds the new / updates the edited event at the schedule. The program issues a query before executing this.

Antenna Scheduler

The Macro Scheduler provies a function to create easily a macro to start tracking at avertain antenna. For this function there are a number of selection fields at the lower right corner of the window, just above the SUBMIT button.



If you change any of the selections *antenna*, *trackmode* or *satellite*, the software replaces the the macro text with a fragment which sets up the antenna for the selected satellite and tracking mode and starts tracking on it. Additional commands / parameter settings may be aded to the macro before the schedule event gets saved by a click do SUBMIT.

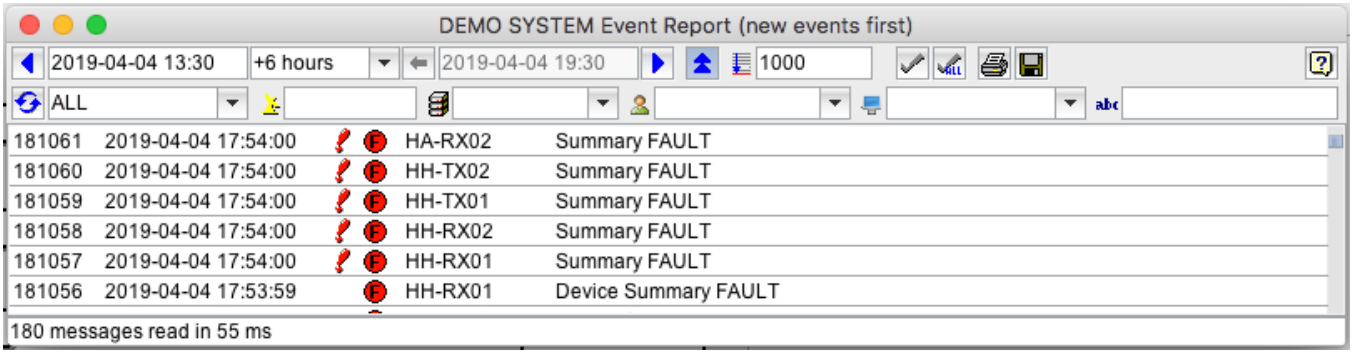
The antenna scheduler function is only available for antennas which are managed by Antenna-Management devices. If there are no such devices configured in the M&C, the fields assigned to the antenna scheduler function apear disabled.

3.10 The Event Report Window

The Event Report window lets you generate filtered reports from the event database maintained by the NMS. This database contains all event (fault) messages issued by the VLCs during the last months (the exact depth of event storage is configurable during system

installation).

The event report shown in the window gets automatically updated when you change the time range to display or the sort order. Changing the filter options in the second line of the toolbar does not automatically update the report, you have to click the reload button or press ENTER in one of the filter fields for this. This lets you combine various filter specifications without being interrupted by the generation of intermediate reports.



Data shown in the list columns

- *column --- description*
- 1 --- The event ID. This is a unique number the software assigns to each event which arrives at the NMS.
- 2 --- The time stamp when the event was originated. The originating VLC sets this, so the time relies on the accuracy of the VLC's clock.
- 3 --- The 'need acknowledgment' mark. Messages showing a red exclamation mark in this column are fault messages which need to be acknowledged by the operator.
- 4 --- The message priority. The message priority decides on the urgency, the message gets delivered from the VLC to the NMS. It also is a search criteria in the Event Report window. The following priority symbols may appear:
  - --- This is an informational message (lowest priority)
  - --- This is a fault message (medium priority)
  - --- This is an alarm message (highest priority, the VLC tries to deliver this immediately, regardless of the dial timing settings)
- 5 --- The primary message source. This usually is the ID of the VLC which issued the message. Messages marked with 'USER' or 'NMS' in this column have been generated locally in the NMS.
- 6 --- The secondary message source. This gives a more detailed information about the source of the message. It may be the name of the device in a VLC which caused the event.
- 7 --- The message text.

Tool-bar Functions

On top of the event report window, there is a 2-line toolbar which lets you control all aspects of what the event report shall contain.

The controls in the upper line between the two blue arrows define the time range to be displayed in the report. For this, the event report windows knows two different modes. One lets you define the time range as start time plus a duration picked from a list of commonly used values. The second mode lets you specify start and end time explicitly. The small button with the horizontal gray arrow symbol lets you switch between the modes. The gray arrow always points to the parameter which is actually active.

The blue arrow buttons enclosing this section of the tool bar let you increase or decrease the start point in increments of the selected duration.

A double click to the start or end time fields opens a calendar dialog window.

The button with the double blue vertical arrows on it toggles the order in which the events are shown. With the arrows down, the newest event is at the bottom of the list, when pointing up the list is ordered from newest to oldest. The default sort order is determined from a parameter set in the "client.properties" file located at the NMS or M&C server. Setting the key "gui.eventSortOrder" to "true" or "false" defines the default behavior of the event report window.

The entry field right of the sort order button defines the maximum number of events one report may contain. There is a default value for this (1000 in most cases), which is a good trade off between performance and the number of events displayed at a time. You may change this limit to your needs, but be aware: reports with millions of events may take some time to be collected.

These buttons lets acknowledge either the selected fault message only or all pending fault messages contained in the event log. Acknowledging a message is always logged as an additional event.

The 'print' and 'save' buttons are quite self-explanatory. 'print' sends the actual report to the printer using the system print dialog of your client computer. Depending on the operating system you are using, you probably have the possibility to preview the print and to select the pages of the report you actually want to be printed.

The 'save' button lets you save the actual report as a CSV file on your client computer. A file

select dialog box pops up, you have to enter or select a file name and click 'save' in order to have the file actually stored. The columns of the CSV file are separated by semicolons, you may import this file for example into a spread sheet program of your choice.

The reload button forces a report to be generated once more, for example to include some new events which may have ocurred since the time when the report was created. During a long lasting query, the button turns into a red 'stop' button, you may click to this to abort a pending query.

The priority selector defines the priority (or type) an event must have to be listed in the report. The selection *ALL* displays all events. *FAULT* includes events which at least have fault priority. *ALARM* displays alarm messages only (see the description of alarm priorities above). The selection *NOT ACK* shows all messages which (still) need to be acknowledged.

This filter lets you filter messages along their primary source. The primary source of a message is the VLC in an NMS environment. For stand alone M&C systems this filter is actually not applicable.

Any non blank value in this field filters those events which have their primary source field (usually the originating VLC) set to this value. If you enter multiple words in this field, all messages are shown which contain *all* words in their primary source at an arbitrary position. The filter is not case sensitive.

If the first character in this field is '-', the filter gets inverted. Example: '-vlc0003' lists all events which do *not* come from vlc0003.

This filter lets you filter messages along their secondary source. The secondary source is usually the name of the device which caused the message. With M&C systems, the entry field for the filter is a combo-box suggesting all device names used in the system in a drop down list. You may enter free text anyhow.

Any non blank value in this field filters those events which have their secondary source field set to this value. If you enter multiple words in this field, all messages are shown which contain *all* words in their secondary source at an arbitrary position. The filter is not case sensitive.

If the first character in this field is '-', the filter gets inverted.

The user name filter lets you restrict the report to messages originated by a certain user. Login messages and messages logging the active change of a parameter are stored with the name of the user who is responsible for this event.

The user name filter is a combo box which lets you either type the name of the user or selected from a drop down list with all known user names at this system. The filter is not case sensitive. You may type only a part of the user name, the filter shows all messages containing this character sequence in their user name field.

Please note, that this filter - if not blank - suppresses all messages which have no user name stored. No faults, no warnings are displayed with this filter.

The client host name filter lets you restrict the report to messages originated from a certain client PC. Login messages and messages logging the active change of a parameter are stored with the origin (hostname or IP4 address) of the event.

The client host name filter is a combo box which lets you either type the name of the client computer or select it from a drop down list with all known client names at this system. The filter is not case sensitive. You may type only a part of the client host name, the filter shows all messages containing this character sequence in their host name field.

Please note, that this filter - if not blank - suppresses all messages which have no client host name stored. No faults, no warnings are displayed with this filter.

The last filter is applied to the message text. Any non blank value in this field filters those events which contain this value in their message text (partial match). If you enter multiple words in this field, all messages are shown which contain *all* words in their message text at an arbitrary position. "one two" as a message filter will match for example the message text "received two ones". The filter is not case sensitive.

If the first character in this field is '-', the filter gets inverted. Example: '-OK' lists all events which do *not* contain OK in the message text.

Remarks

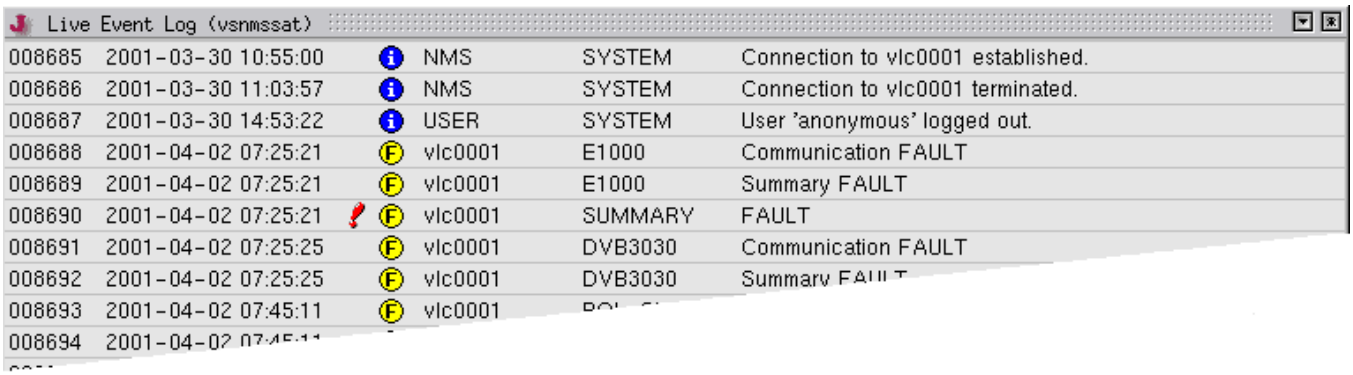
- The messages appear sorted by the time when they were originated.
- If you click to a message in the report, the time when the message was received at the NMS is displayed in the status line at the bottom of the window.
- With the right mouse button you get a context menu on each event, providing additional functions depending on the event's contents.
- The filter functions are combined using a logical AND. The report contains those events of the selected time range which match all of the filters.
- A new report is generated with the actual filter settings if you press ENTER in one of the entry fields or if you click to the reload button.

3.11 The Live Event Log Window

The Live Event Log window shows the recent event messages as they are received from one of

the VLCs. Unlike the Event Report window , which sorts the events by the when they were originated, the Live Event Log window shows the messages in the order of their arrival at the NMS. The window has a fixed size and always shows the last 25 messages.

The sort order of the event list (newest first / oldest first) may be toggled using the context menu shown with a right mouse button click on any line of the list. The default sort order is determined from a parameter set in the "client.properties" file located at the NMS or M&C server. Setting the key "gui.eventSortOrder" to "true" or "false" defines the default behavior of the live event log window.



Data shown in the list columns

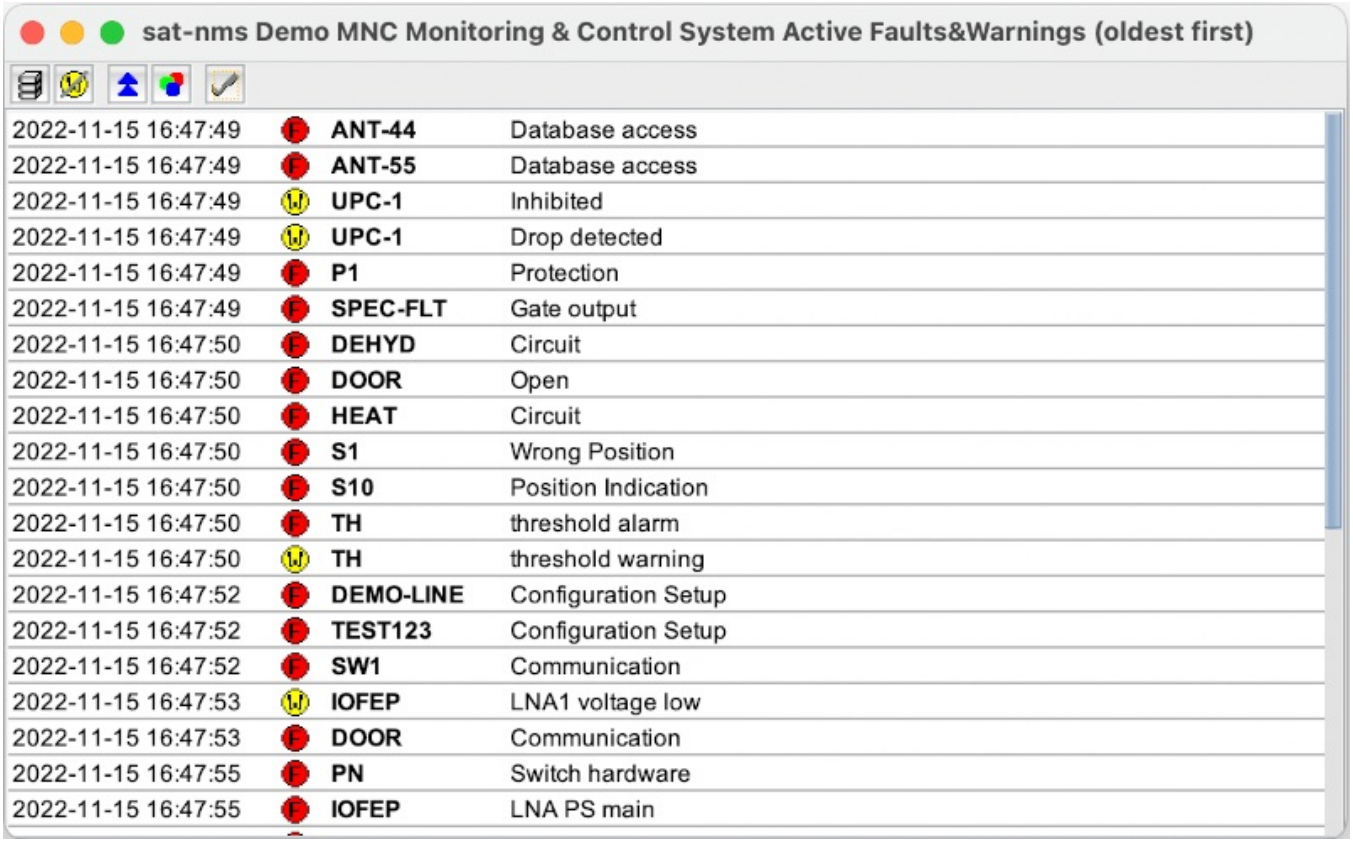
- Column 1 --- The event ID. This is a unique number the software assigns to each event which arrives at the NMS.
- Column 2 --- The time stamp when the event was originated. The originating VLC sets this, so the time relies on the accuracy of the VLC's clock.
- Column 3 --- The 'need acknowledgment' mark. Messages showing a red exclamation mark in this column are fault messages which need to be acknowledged by the operator.
- Column 4 --- The message priority. The message priority decides on the urgency, the message gets delivered from the VLC to the NMS. It also is a search criteria in the Event Report window. The following priority symbols may appear:
  - --- This is an informational message (lowest priority)
  - --- This is a fault message (medium priority)
  - --- This is an alarm message (highest priority, the VLC tries to deliver this immediately, regardless of the dial timing settings)
- Column 5 --- The primary message source. This usually is the ID of the VLC which issued the message. Messages marked with 'USER' or 'NMS' in this column have been generated locally in the NMS.
- Column 6 --- The secondary message source. This gives a more detailed information about the source of the message. It may be the name of the device in a VLC which caused the event.
- Column 7 --- The message text.

You may acknowledge messages marked with the red exclamation mark by double-clicking to the message line. This makes the exclamation mark disappear, an acknowledgment message gets added to the end of the log.

Please note, that if you close the Live Event Log window and open it again, any acknowledged message will appear with the exclamation mark set again. This is because the recognition of acknowledged messages depends on message sorting which does not happen in this window.

3.12 The Active Faults Window

The Active Fault Windows lists all actually pending faults and warnings in the VLC / M&C. The window automatically updates its content as the faults appear or disappear.



The toolbar buttons of the window let you select how the window displays the list of active faults:

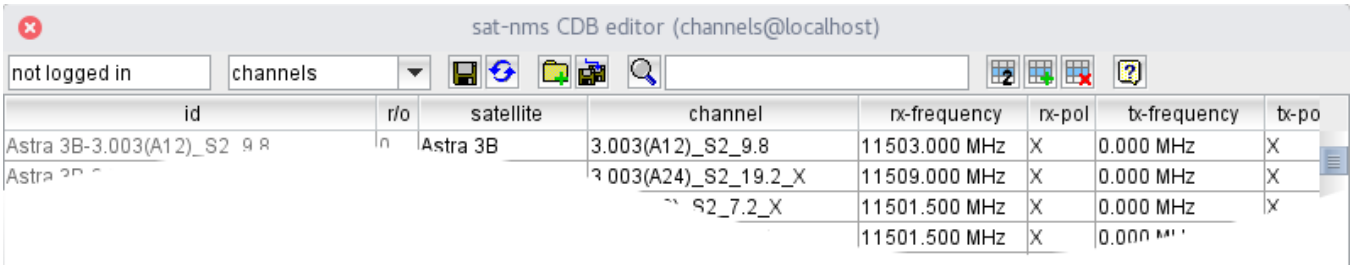
	If pressed, the faults are grouped by device name, if not they appear sorted by date.
	If pressed, the window suppresses al warnings, shows faults only. If not, faults and warnings are displayed.
	If pressed, newest events are shown on top. If not, oldest events are shown first.
	If pressed, the background of each line gets colored red for faults, yellow for warnings.

✔	Makes the "new fault" mark in the main window disappear and silences the beeper.

3.13 CDB Central Database Table Editor

The text based channel database (CDB) is a legacy tool to mangage satellite channel rx-/tx-parameter in a conveient way. It has been replaced with a SQL based database solution which entirely is operated through the sat-nms Web client. The description below is contained in the manual for reference only, it may apply to older M&C installations using the sat-nms Java client.

The sat-nms CDB table editor is a versatile tool to manage satellite channel lists in an easy and clear way. The table editor displays the contents of the CDB in spreadsheed like layout, lets you edit, add or delete channel definitions. Beside this, the table editor may be used to export or import the CDB table or parts of it on your client PC.



The picture above shows the table editor's toolbar. Below you find a short reference for all functions which are accessible here. A more elaborate description of the table editor's capabilities you find at the paragraphs forther down at this page.

- --- The login field. To log in, click into the field and enter your user name / password in the dialog popping up. You need to be logged in to save the edited table back to the server, all other functions work without login als well.
- --- The database selection. The M&C server may maintain other database tables beside the satellite channel list. Using this drop down selection you may switch between these databases. With your sat-nms installation, the field may be missing or limited to the 'channels' selection only.
- --- Saves the edited table back to the server. You need to be logged in for this.
- --- Reloads the table from the server. This abadons all changes since you opened the editor (or since the last save).
- --- Opens the import dialog. Lets you read a CSV file with channel definitions from you local PC and import these definitions into the CDB.
- --- Opens the export dialog. Lets you export all channels (or only the selected ones) to a CSV file on you client PC.
- --- Toggles the search function. Requires a search pattern to be entered in the field at its right.
- --- The search pattern field. Enter a search pattern here to select all channels matching this pattern. See 'Searching channels' below for a more detailed description how seaching works.

- --- Duplicate row. Makes a duplicate of the (topmost) selected channel.
- --- Add row. Inserts new channel definition above the (topmost) selected channel. The new channel gets initialized with default settings.
- --- Delete row(s). Deletes the selected channel or all selected channels if more than one is selected.
- --- Shows this help page.

Document style workflow

The table editor handles the CDB table like a document. When you start up the editor, it requests the complete database contents from the server and presents it in the editor window. It does not change the database until you click the save button to write back the changed channel list to the server. At this point all devices using the channel table will be informed about the changed database.

This workflow implies two things:

1. You can safely play around with the editor, change, delete or add channel definitions without disturbing the normal operation of the station. At any point you can abadon the editing process without changing the original data.
2. If two persons edit the database using two instances of the table editor at the same time, only the changes saved lastly will be taken by the CDB. This is the same as two persons edit the same document on a shared drive: The one wins who saves the changed document al last.

Logging in

A login as a user with a privilege level 100 or higher is required to write a modified table back to the server. All other functions, viewing channels, exporting them etc. are possible without login.

Login is done quite similar to the sat-nms M&C software, simply click to the login field in the upper left corner of the window and enter your user name and password at the dialog popping up.

Selecting the database

Some software installations may use multiple CDB databases, e.g. one for satellite channels and another for BISS keys. These installations show a selection field for the database to edit beside the login field. This field may be missing with your software installation.

Sorting the channels

The table editor normally presents the channels sorted alphabetically by the channel ID. By clicking to a column header of the table, you may sort the table by this column, e.g. by receive frequency. Clicking again to the table header reverts the sort order. Clicking to the header of the first column (channel ID) restores the original sort order.

Searching channels

When entering a text in the search field of the tool bar, the editor highlights all channels which contain this text in their channel ID. Beside this more complex searches are possible:

- Multiple words separated by space characters are searched and combined with a logical AND: "astra S2" for example marks all channel containing "astra" AND "S2" in their channel ID.
- Search words may be prepended by the name of a table column (as shown on the table header) followed by a colon. This makes the program search this word in this column. Example "EUT07 fec:7/8" marks all channels which contain "EUT07" in their channel ID and have a fec "7/8" set.
- The search is not case sensitive. The 'Search' button beside the search field toggles the selection

Selecting channels

A single channel is selected by clicking somewhere into the table row representing this channel. Holding down the SHIFT key while clicking to another table row selects a range of channels between these rows. Holding down the CTRL key while clicking to some channels adds these channels to the selection (or removes them if they are already selected).

Editing channels

You may change any channel parameter 'in place' in the table. For selection parameters simply click to the parameter field and select the new value from the drop down list. For numeric or textual parameter you need to double click the table field to switch it to edit mode. As soon as one value has been changed, the "MODIFIED" indicator shows up at the upper right corner of the window.

When you change the satellite name or the channel name, the program makes a new channel identifier from this and checks if this identifier is unique in the channel list. If not, a suffix is added to the channel name to make the identifier unique and a warning ist displayed.

If you are using the 'Import EBU channels' at the RX-Channel device, the channels imported from the EBU channel list are marked read-only anf cannot be edited in the table editor.

Adding new channels

There are two options to add a new channel to the database. 'Add a channel' means to add a new channel named 'NEW' and filled with defaults for all parameters. The second way to add a new channel is 'Duplicate channel'. As the name suggests, this duplicates the selected channel. All parameters are copied from the source channel and a suffix is added to the channel name to make the channel ID of the new channel unique. The new channel gets added above the actually selected row. If multiple rows are selected, the new channel is added above the topmost selected channel, this also acts as the template for the 'duplicate' function

Deleting channels

To delete one or more channels from the table, select the channels to delete and then click the 'delete row' button in the tool bar.

Importing channels

The table editor permits to import a set of channels from a CSV file which is located at your client PC. To import a file, click the 'import' button in the tool bar, select the file in the dialog box popping up and finally click 'Open' in this dialog box.

The table editor imports the file and adds the database records defined in this file to the table. It does this in an intelligent way:

- If an imported record has a duplicate in the table which matches the imported one for all parameters exactly, the imported channel definition is discarded. No duplicate is created in this case.
- If the imported channel has a duplicate in the table with the same channel ID but with different parameters, the channel gets imported and the channel name gets a '_DUP' suffix added.
- All other records in the imported file are simply added to the table.

The file format the import function expects, depends on your software installation and software version. It is always safe to import files which have been created using the export function on a sat-nms M&C with the same version number.

Exporting channels

You may export either all channels in the table or a subset of them to a local CSV file. Select the files to export and click the 'export' button in the tool bar. Then select or enter the file name you want to save to an click 'Save'.

If no channels are selected, the software exports all channels. You may use the search button (the magnifier glass) to remove an existing selection. If only one record is selected, the software will export this record only.

Saving the changed table

The 'save' button writes the changes you made back to the CDB server. You need to be logged in with a privilege level of at least 100 to do this operation. Once you click 'save', all RX-Channel and TX-Channel devices in the M&C get informed about the changed channel list.

If you made changes to the table and close the editor without saving the table, the program shows a warning about this.

Reverting all changes

The table editor offers the 'reload' button in the tool bar to discard all changes ant to load the table again from the CDB server. You may want to use this if you accidentally messed up the channel table.

3.14 The sat-nms ACU Indoor Unit

The ACU indoor unit is a PC system based on the sat-nms M&C technology. Together with an antenna controller and a beacon receiver it builds the sat-nms antenna control system. Main

features of this are:

- Monitoring and control of the concerned equipment.
- Satellite tracking using step track and orbit prediction tracking methods.
- Analysis and graphical presentation of the satellite tracking performance.

Using the sat-nms M&C platform as the basis, the ACU indoor unit also includes a lot of the benefits of the basic software:

- The software is highly modularized. The subsystems interfacing the tracking engine to the outside world may be configured to control third party products instead of the sat-nms outdoor unit or the beacon receiver.
- The user interface is very clear and contains data analysis tools to display in which way the antenna tracked the satellite.
- As with other implementations of the sat-nms M&C Software, the user interface is an platform independent Java program which may by run on any other computer in the LAN than the indoor unit itself.
- The indoor unit provides a event log database with a HTTP based interface to third party software.

The following chapters explain the concepts behind the sat-nms antenna control system and the architecture of specific configurations of the ACU. This is supplemented by a detailed description of all user screens and the meaning of all adjustable parameters.

3.14.1 Concepts

SatService GmbH offers sat-nms ACU Indoor Unit in two general configurations:

- The first configuration is optimized to work together with the sat-nms ACU/ODM. It utilizes all features of this device and adds a comfortable user interface with some handy utilities to it. The basic tracking functions are handled by the ODM in this case.The chapter 'sat-nms ACU Indoor Unit & Outdoor Module Configuration' describes the functionality and architecture of this configuration, chapter 'The ACU Main Window (with sat-nms ODM)' the appendant user interface. Furthermore you find a full description of the sat-nms ACU / ODM in the document 'sat-nms ACU Outdoor Module / User Manual'.
- The second configuration is directed to applications where the antenna pointing controller is a third party product. In this configuration the ODM / pointing controller is solely used to position the the antenna. All tracking algorithms are performed by ACU indoor unit software.Chapter 'sat-nms ACU Indoor Unit & 3rd Party Controller Configuration' describes the functionality and architecture of this second configuration, chapter 'The ACU Main Window (with 3rd Party Controller)' the appendant user interface. This modularity and flexibility makes the sat-nms ACU Indoor Unit to a universal antenna controller with sophisticated tracking capabilities which can be used with a multitude of antennas. Due to it's configurability it can be deployed together with new antenna installations and as an upgrade for existing antenna systems as well.

3.14.1.1 Tracking Modes

The sat-nms antenna control system -- regardless of the configuration used -- provides the basic types of satellite tracking:

Step Track

In plain step track mode, the ACU performs small test steps with the antenna in regular intervals to see if the receive level becomes better or worse for another antenna position. With the knowledge of the antenna pattern's shape, the tracking engine computes an optimized position from measurements taken at the old position and at the new one. Many parameters such as the step size, averaging times and the overall repetition interval are configurable by the operator.

Adaptive Track

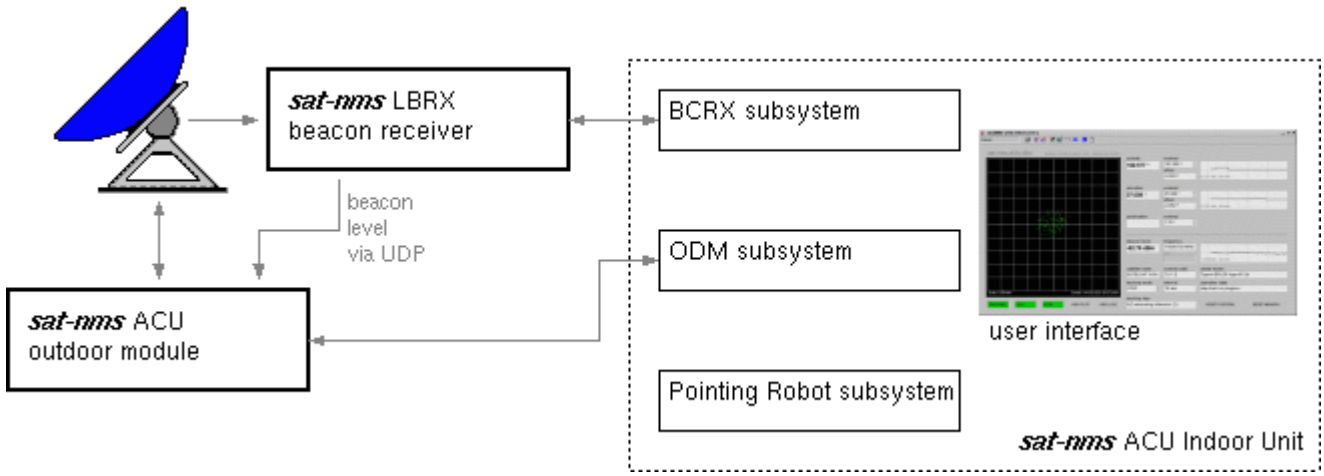
The adaptive tracking mode works much like the plain step track, however the tracking engine in background computes a mathematical model of the antenna motions from the step track results. A great advantage of this mode is that the antenna follows the computed model even if the beacon reception fails. With the plain step track mode, the antenna would freeze in this case until the satellite beacon appears again.

Program Track

With the third tracking mode called program track, the antenna follows a position computed from the satellite's ephemeris data. The tracking engine accepts Keplerian elements in NASA 2-line format or the proprietary Intelsat ephemeris data format for this. For this tracking mode, no beacon reception is required, however the ephemeris data sets must be updated every few days.

3.14.1.2 sat-nms ACU Indoor Unit & Outdoor Module Configuration

The diagram below shows the architecture of a antenna control system entirely built of sat-nms components. The 'sat-nms ACU Outdoor Module' controls the antenna pointing and performs the steptrack and adaptive tracking modes. The 'sat-nms LBRX Beacon Receiver' measures the satellite beacon level and supplies this level value on the Ethernet vie UDP Packets to the ODM. Both devices are controlled by the IDU through an Ethernet network (strictly spoken, the ODM also communicates with the beacon receiver directly, but this is for synchronization purposes only).



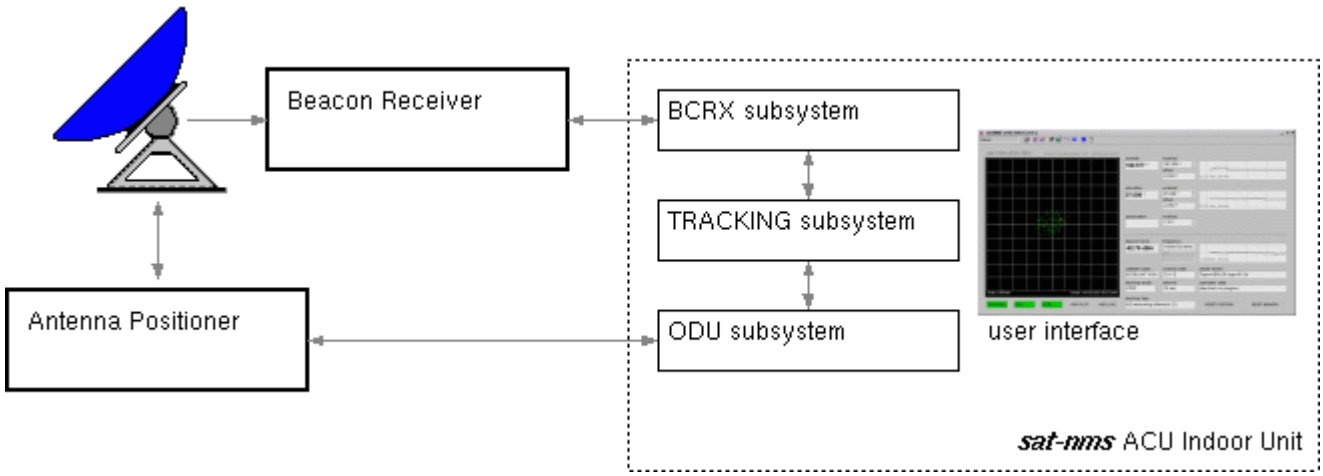
The indoor unit provides a comfortable graphical user interface which permits to monitor and control the whole antenna system. Beside this, it contains the so called 'Pointing Robot' , a software module which controls the antenna pointing according to the data evaluated from satellite ephemeris data sets or read from tables. This versatile tool superseeds the PROGRAM-Track function built into the ODM, which is not used in this configuration.

Configuring the antenna control system in this way is the favored solution. It achieves the best tracking results. More benefits are:

- The components of the antenna control system are optimally coordinated.
- Doing the step track locally in the ODM allows a very close timing of the operations during a steptrack cycle, this makes the tracking less susceptible to atmospheric variations of the beacon level.
- The tracking is completely independent from the indoor unit. If the IDU fails, the ODM still tracks the satellite.

3.14.1.3 sat-nms ACU Indoor Unit & 3rd Party Controller Configuration

The diagram below shows the architecture of a antenna control system using third party components. The 'Antenna Positioner' device solely controls the antenna pointing, it does not perform any satellite tracking. The 'Beacon Receiver' measures the satellite beacon level. Both devices are controlled by the IDU using arbitrary M&C interfaces (serial, TCP/IP). Any tracking functions are performed by a software module in the sat-nms ACU IDU.

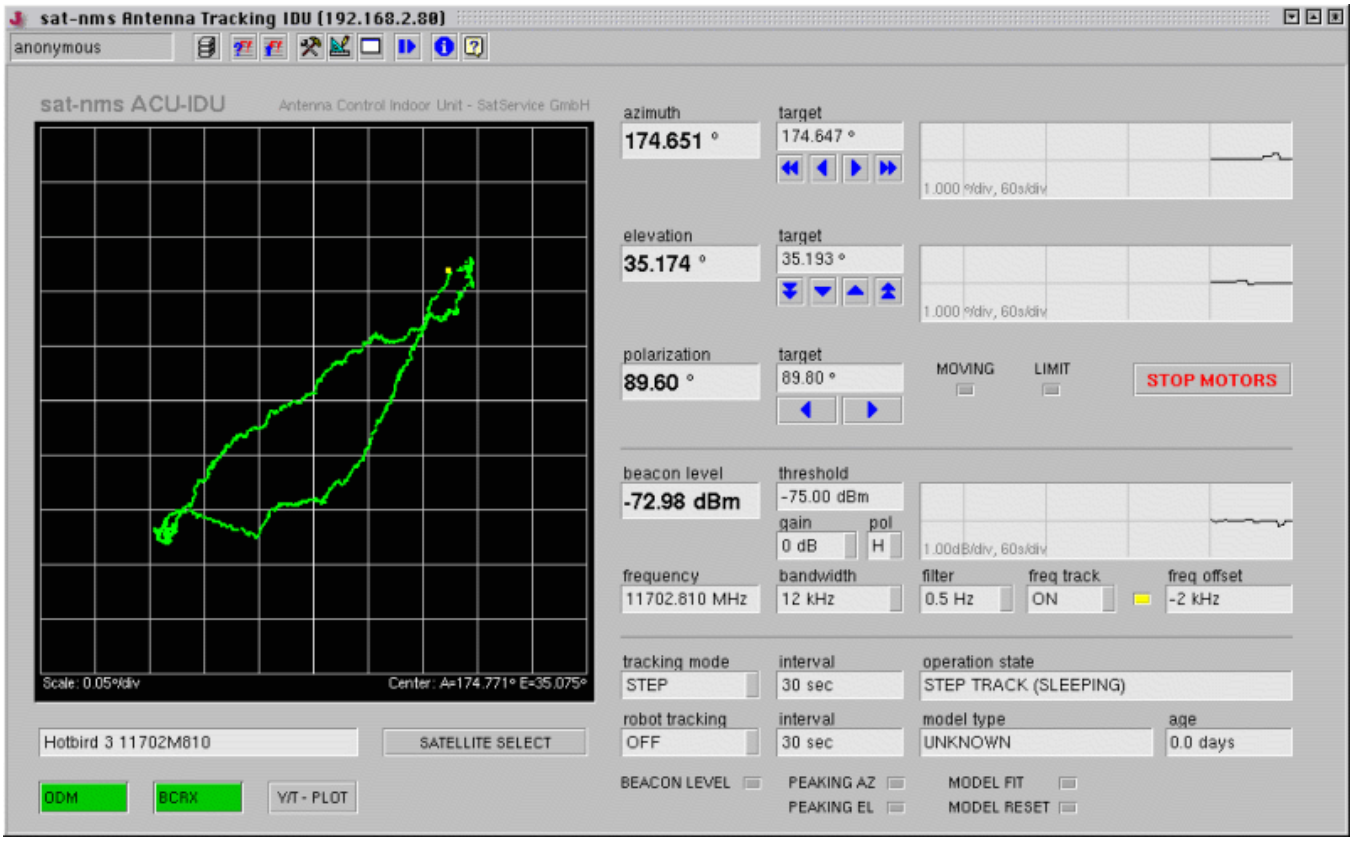


The indoor unit's main task is to perform the satellite tracking in this configuration. The IDU reads the beacon level thru the receiver's M&C interface and directs the antenna to to tracking steps. The tracking algorithms used by the IDU are similar to those used by the ODM, but not exactly the same. This is mainly because there is a longer time between moving the antenna for a test step anf reading out the beacon level.

The main advantage of this configuration is it's flexibility. The IDU is capable to do all tracking modes with any antenna controller which can be remote controlled by the sat-nms M&C system, the same applies for the beacon receiver. The sat-nms ACU indoor unit is a cost effective solution to upgrade existing antenna systems with a modern, network based user interface and a powerful satellite tracing engine.

3.14.2 The ACU Main Window (with sat-nms ODM)

The main screen of the sat-nms ACU Indoor Unit shows the main parameters of the antenna tracking control similar to the front panel of a oscilloscope. The left part of the window contains a diagram which shows the antenna movements of the past 48 hours. The most important settings and status displays are located at the right.



The toolbar on top of the window gives access to user login/logout, the event log and some other functions. As the ACU indoor unit inside principally is a M&C system, the toolbar is exactly the same as for the M&C Main Window .

At the top of the right part of the window thepointing display is located. It shows the actual antenna pointing and a strip chart of the recent history of antenna movements. Below the pointing display you find the beacon level display It reports the actual beacon level in a similar way. At the bottom of the right side the window contains an area with the tracking status display . Finally, below the tracking diagram on the left side, the ACU main screen contains the ACU subsystem menu . These buttons give you access to subsystem screens with all detail parameters of the ACU / tracking.

3.14.2.1 The Pointing Display

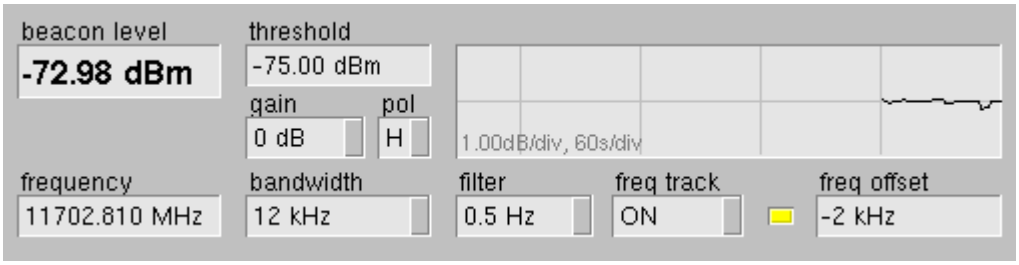
The area in the upper right part of the window shows the actual antenna pointing and provides entry fields to move the antenna to a given position. The example below is taken from an antenna which is not equipped with a polarization motor, the polarization angle display is empty therefore.

The fields labeled 'azimuth', 'elevation' and 'polarization' show the actual antenna pointing as read out from the angle encoders. For azimuth and elevation there is also a strip chart display of the angle. If you choose a high resolution scale for the chart, you can watch the antenna doing the tracking steps in the chart. Click with the right mouse button into the chart to get a pop-up menu for scales and other display options.

The 'target' fields show the actual target values. The arrow buttons below these fields permit to adjust the antenna position in small or larger steps. This only should be done with any tracking switched off to avoid interferences with motions initiated by the tracking engine.

3.14.2.2 The Beacon Level Display

Below the antenna pointing, the ACU shows the actual beacon level. The level value shown is that one read by the ODM from the analog input. This value may differ from the level reported by the beacon receiver directly. There is also a strip chart display of the level. The chart moves with the same speed as the angle charts above, so you directly can watch the influence of tracking steps to the beacon level. A click with the right mouse button into the chart shows a pop-up menu for scales and other display options.



The screen also provides fields to set common parameters of the beacon receiver like the receive frequency and polarization, bandwidth parameters and the frequency tracking option. Changing the values in these fields changes the beacon receiver setting immediately.

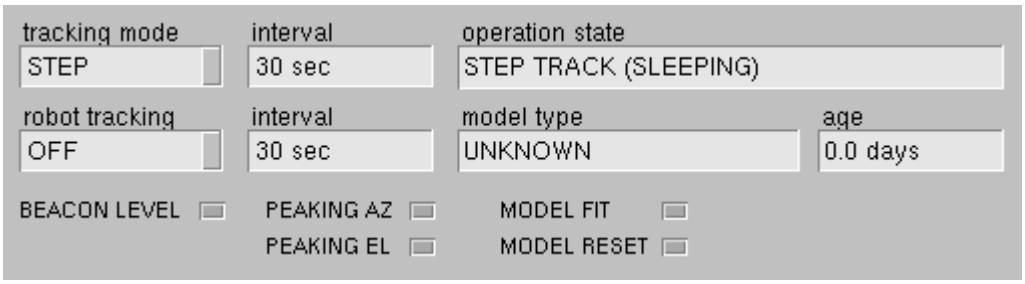
The threshold value contained in this parameter group is the ACU/ODM level threshold rather than the threshold parameter of the beacon receiver itself. The latter is recommended to be

set to a very low value in order to avoid level fault messages from the beacon receiver. The beacon level threshold is to be monitored by the ACU/ODM, hence the level fault can be synchronized with the tracking activities.

The frequency offset display in this group reports the activity of the beacon receiver's frequency track facility, the small yellow lamp is lit while a frequency track cycle is in progress

3.14.2.3 The Tracking Status Display

The lower right area of the ACU main window shows the tracking status display and the basic tracking mode parameters.



The table below gives a short description of each parameter in this area.

- **tracking mode** --- With this parameter you set the basic tracking mode. Available modes are OFF, STEP and ADAPTIVE. This parameter is passed to the ODM.
- **interval** --- With this parameter (upper row) you define in which intervals the ACU shall perform tracking steps. This parameter is passed to the ODM as well.
- **operation state** --- This field shows the general operation state of the tracking engine.
- **robot tracking** --- This switches the pointing robot ON or OFF. If the pointing robot is activated, the tracking mode is forced to OFF anf the antenna of moved on a path evaluated by the robot.
- **interval** --- The interval parameter in the lower row controls the update rate of the pointing robot.
- **model type** --- This status field displays the type of algorithm the pointing robot actually uses. Possible data sources may be Keplerian elements (NASA 2-line format), Intelsat ephemeris data or list of positions defined in a text file.
- **model age** --- Displays the age of the data used by the robot. With ephemeris data sets this is the time since the epoch of the data set. For file tracking the time stamp of the last record in the table is used as the epoch.

Below these parameter fields a couple of fault indicators (red lamps) are located on the screen. They report any faults of the tracking engine. The meaning of the individual faults are:

- BEACON LEVEL --- The beacon level is below the threshold and one of the tracking modes STEP or ADAPTIVE is selected. In STEP track mode the antenna freezes in this situation, in ADAPTIVE mode the antenna is moved along the model which has been calculated before the beacon disappeared.
- PEAKING AZ/EL --- The step track peaking failed for one of the axes. The tracking engine reports this fault if the position / beacon level pairs measured during the tracking cycle

does not match the antenna pattern curve sufficiently. This may happen if the beacon values are too noisy or if there is no beacon reception at all and the threshold is adjusted too low.

- MODEL FIT --- If the variance of the measured peaks to the calculated model exceeds the 'jitter threshold' value, this fault is raised. This is an indication that either the measurement values are noisy or the model type is not appropriate for the satellite's motion.
- MODEL RESET --- If the ODM recognizes a 'MODEL FIT' fault at three consecutive tracking cycles, it presumes the model to be invalid and resets the model. This voids all recorded step track positions (they remain visible in the diagrams) and resets the tracking to the learning phase where no model is available.

3.14.2.4 The ACU Subsystem Menu

The icons below the tracking diagram are the ACU subsystem menu. They give access to some less frequently used parameters of the antenna control system.

Clicking to the ODM icon opens a window which permits access to all parameters of the ODM directly. Also the the color of the icon signals the fault state of the ODM device. With the ODM device window there are a couple of parameters which control the behavior of the tracking subsystem. Chapter 'The ODM Detailed Parameter Screens' gives a detailed description of them.

The BCRX icon opens a window directly to operate / configure the beacon receiver attached to the ACU. This window is required to set some beacon receiver parameters which are not accessible thru the application main screen.

The 'VIEW PLOT' button opens a separate graphical Y/T display window which gives more detailed information about what the tracking engine did during the recorded hours. It provides variable scales, and permits to display additional information. The display shows either the azimuth or the elevation pointing found at the beginning of each tracking step together with the beacon level measured at this time. The following additional information may be included to the diagram:

- --- This button has no function in this configuration.
- --- The main pointing graph (light green) always shows the pointing the antenna was really moved to. This is the smoothed position if smoothing is activated. If this toolbar button is pressed, the diagram includes the evaluated peak positions as a faded, dark green graph.

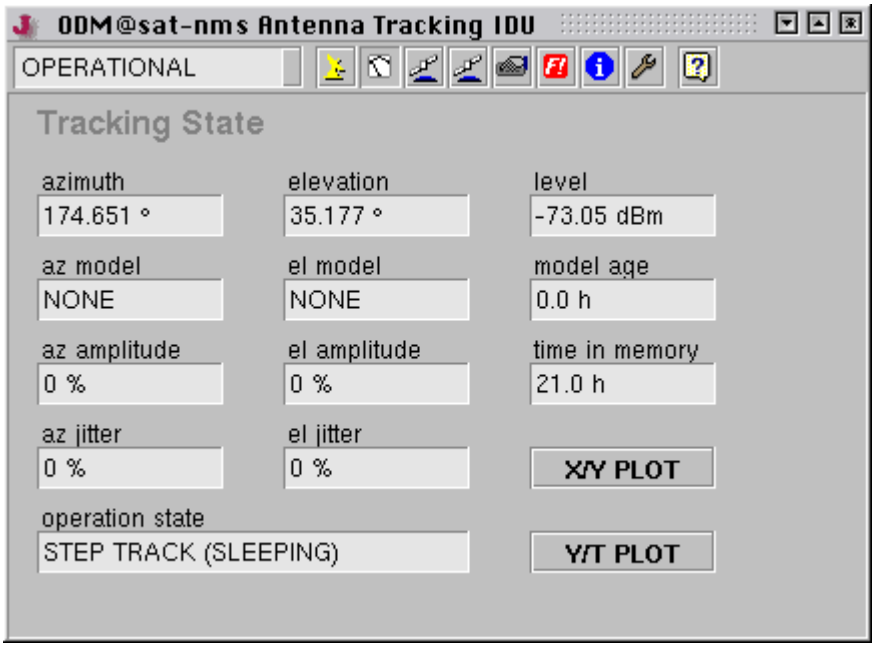
Clicking to the 'SATELLITE SELECT' button opens a window which lets you store and recall the position and the tracking parameters of several satellites. Also the ephemeris data for the pointing robot are entered here. Chapter 'The Satellite Select Screen' explains the functions of

this screen.

3.14.2.5 The ODM Detailed Parameter Screens

The ODM detailed parameter screens are part of the M&C device window for the SatService ACU/ODM. This window integrates all status and control parameters which are available for the ODM. To monitor and control the tracking functions of the ACU, the following two screens are important:

Clicking to the meter symbol in the toolbar shows the tracking state page. It displays a number of state parameters which report what the tracking engine actually does.

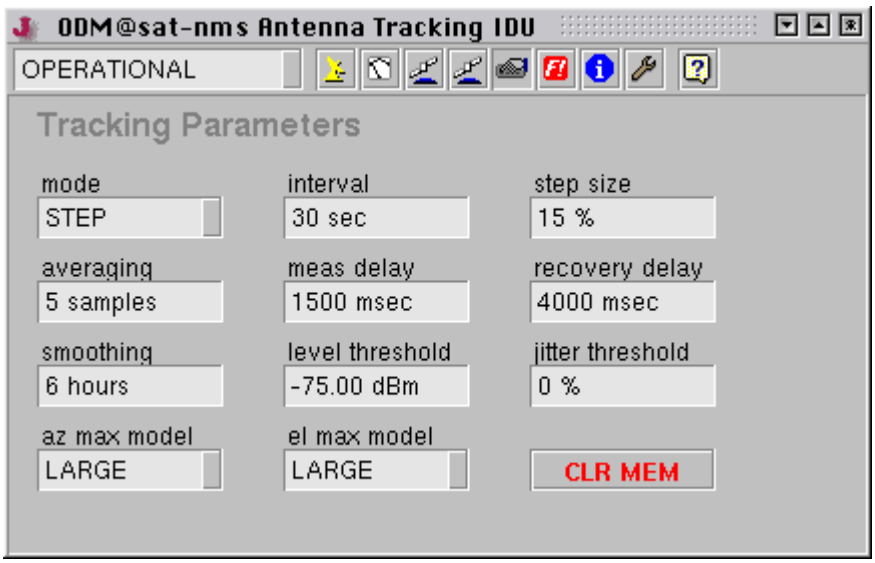


- **azimuth** --- The actual azimuth pointing.
- **elevation** --- The actual elevation pointing.
- **level** --- The actual beacon level (read from the ODM's analog input).
- **az model** --- The model type the ODM uses for the azimuth axis in ADAPTIVE mode if the beacon is lost. The value is displayed all the time, even if the beacon level is OK.
- **el model** --- The same for the elevation axis.
- **model age** --- This displays the time since the adaptive models have been updated the last time. The value normally is zero, if the beacon disappears it counts the time the antenna is tracked using the model.
- **az amplitude** --- The amplitude of the azimuth motion as a percentage of the antenna's 3 dB beamwidth. The ODM approximates the motion by a simple sine function to determine the amplitude.
- **el amplitude** --- The amplitude value for the elevation axis.
- **time in memory** --- The time span covered by the tracking data the ACU has in it's memory.
- **az jitter** --- The variance of all steptrack positions in memory with respect to the modeled values (azimuth). This is a measure how good the model fits. The jitter value is in percent if the antenna's 3 dB beamwidth. The 'jitter threshold' setting refers to the 'az/el jitter

values.

- **el jitter** --- The same for the elevation axis.
- **X/Y PLOT** --- Clicking to this button opens a separate window showing the same X/Y diagram as displayed in the main window.
- **operation state** --- Shows what the tracking engine actually is doing.
- **Y/T PLOT** --- Clicking to this button opens separate window showing the same X/T diagram as can be accessed from the main window.

Clicking to the device control symbol in the toolbar shows the tracking parameter page. Beside the tracking parameters shown in the application main window this page displays all adjustable parameters of the tracking subsystem.



- **mode** --- The tracking mode parameter selects the tracking method, the ACU actually uses. Possible selection are:
  - **OFF** --- No tracking is performed.
  - **STEP** --- Step track mode. In regular intervals, the antenna performs small search steps to optimize the pointing.
  - **ADAPTIVE** --- The adaptive tracking mode works the same way as step track, but it additionally is capable to predict the satellite's position when the beacon reception fails. It computes mathematical models of the satellites motion from the step track results recorded over a certain time.
  - **PROGRAM** --- The program tracking mode is offered here only for compatibility purposes only. In conjunction with the IDU the pointing robot should be used rather than the program track mode of the ODM.

A full description of the tracking functions used in the sat-nms ACU is given in chapter '5.0 Theory Of Operation' of the ACU/ODM manual.

- **interval** --- The interval time specifies how often the ACU shall perform a step track cycle. The value is to be entered in seconds. In fact, the parameter does not specify a cycle time but the sleep time between two tracking cycles. This means, the true cycle time is the time the ACU needs to perform one step track cycle plus the time entered

here. 300 seconds (5 minutes) is a good starting value for this parameter. Inclined orbit satellites probably will require a shorter cycle time, very stable satellites can be perfectly tracked with one step track cycle every 15 minutes (900 seconds).

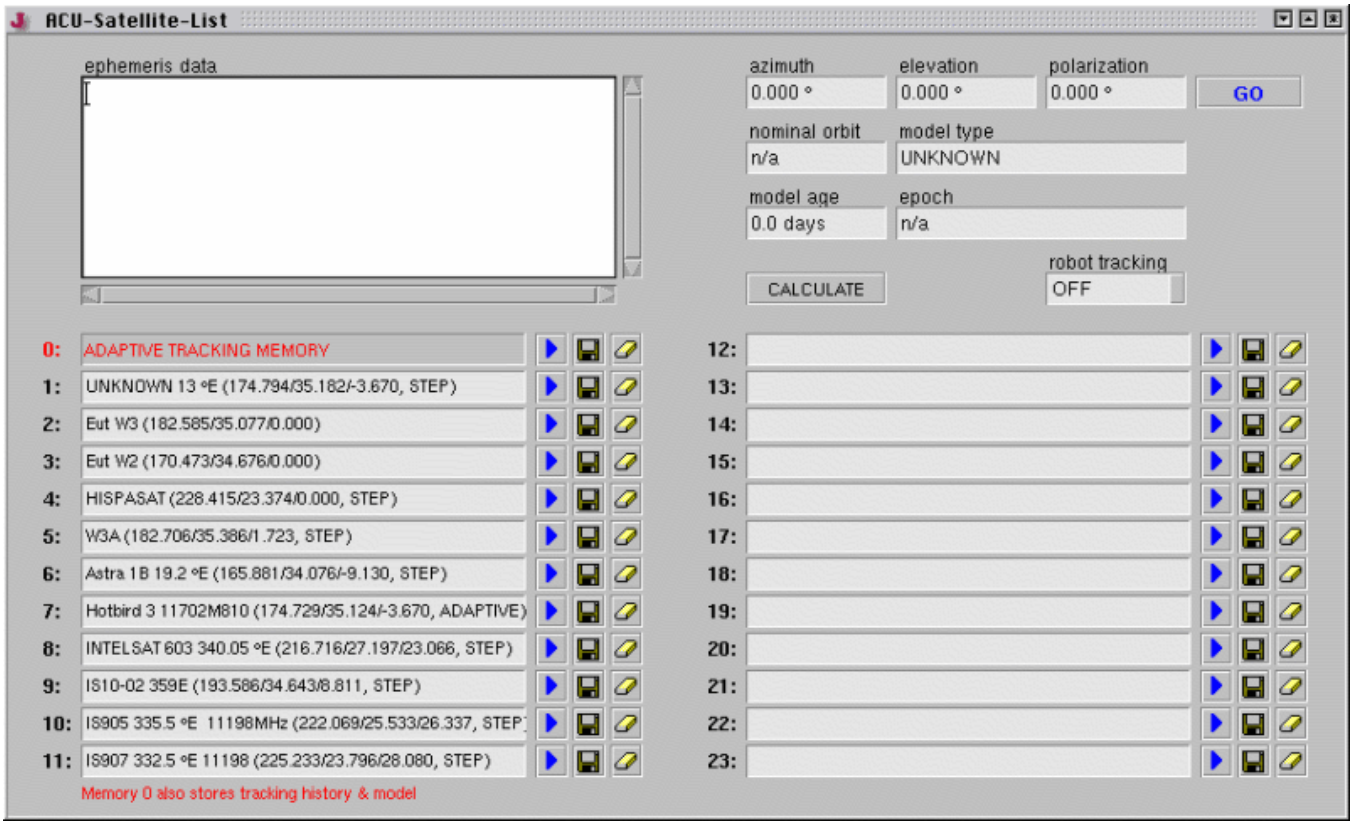
- **stepsize** --- The tracking step size is a very important parameter for the performance of the tracking. It defines the size of every de-pointing step, the ACU makes in order to find out where the optimal antenna pointing is. Setting too high values will cause significant signal degradations during the step track cycle because the antenna moves a too large amount away from the satellite. Setting the value too small will let the beacon level jitter mask the level differences caused by the test steps, the antenna will not track the satellite properly.The step size is specified as a percentage of the antenna's half 3dB beamwidth. The ACU calculates the beamwidth from the antenna diameter and the beacon frequency. Expressing the step size in this relative way keeps the value in the same range, regardless of th type of antenna. The recommended value for this parameter is 15-20%. You may want to start with 20% and try to reduce down to 15% if the signal degradation during tracking becomes too high.The tracking step size is a common parameter for both axes. If both axes behave differently, you can tweak the antenna diameter settings in the setup. Specifying a larger diameter makes the ACU using a smaller step size for this axis.If the tracking step seem to be completely out of range, you should check if the beacon frequency is set properly. The frequency must be the true receive frequency at the antenna, entered in MHz, not an L-band frequency or other IF.
- **averaging** --- When measuring the beacon level, the ACU takes a number of samples and averages them. The standard value of 5 samples normally should not be changed. Larger values will slow down the ACU execution cycle.
- **measdelay** --- During a steptrack cycle, the ACU positions the antenna to a certain offset and then measures the level. Between the moment when the antenna reached commanded position and the beacon level measurement the ACU waits some time to let the beacon level settle. The optimal delay value depends on the beacon receiver's averaging / post detector filter setting and is a quite critical for the steptrack performance.If the delay is too short, the beacon voltage does not reach its final value, the steptrack does not properly recognize if the signal gor better or worse after a test step. If the delay is too long, the impact of fluctuation to the measures level grows and may cover the small level difference caused by the test step. With the sat-nms LBRX beacon receiver, best results are achieved if the receiver is set to 0.5 Hz post detector filter bandwidth and a measurement delay of 1500 msecs
- **recoverydelay** --- After the the ACU has done the tracking steps for the elevation axis, it waits some time before it starts tracking the azimuth axis. This is to let the beacon level settle after the final position has been found. A typical value for this parameter is 4000 msecs
- **smoothing** --- This parameter controls the smoothing function. Setting it to zero disables smoothing. Smoothing lets the ACU point the antenna to positions evaluated from a simple model calculated from the step track peaks of the recent few hours. To understand the functionality of the smoothing function you may want to read chapter '5.3.3 Smoothing' in the ACU/ODM manual.
- **levelthreshold** --- If the beacon level falls below this threshold value, the ACU does not perform a step track cycle. If the level falls below the threshold during the steptrack cycle, the cycle gets aborted.If the ADAPTIVE tracking ist enabled and there is enough

data in the tracking memory, the ACU computes a mathematical model from the stored data and predicts the antenna pointing position from the extrapolation of the model. If the tracking mode is set to 'STEP', the ACU leaves the antenna where it is if the beacon level drops below the limit.Adjusting the threshold level that adaptive tracking is switched as expected must be done carefully and may require some iterations, specially if the beacon is received with a low C/N. A good starting value for the threshold is 10 dB below the nominal receive level or or 2 dB above the noise floor the beacon receiver sees with a de-pointed antenna, whatever value is higher.To turn off the monitoring of the beacon level (this in fact inhibits the adaptive tracking), simply set the threshold the a very low value (e.g. -99 dBm)

- **jitterthreshold** --- If the jitter value of at least one axis exceeds this threshold, the ACU raises an 'model fault'. If this happens three consecutive times, the ACU resets the models of both axes. Adaptive tracking will be possible not until 6 hours after this happens.A typical threshold value is 20%, this will detect very early that a model does not fit to describe the satellite's motion. If this value causes false alarms too often, you may want to raise the threshold to 50%. Setting it to 0 switches the threshold monitoring completely off.
- **azmaxmodel elmaxmodel** --- These settings let you limit the adaptive model to a simpler one, the ACU would choose by itself. The maximum model type can be set individually for each axis. Normally you will set both axes to 'LARGE', which leaves the model selection fully to the the ACU's internal selection algorithms.In cases where the ACU seems to be too 'optimistic' about the quality of the step track results, the maximum model on one or both axes may be limited to a more simple and more noise-resistant model. Specially inclined orbit satellites which are located close to the longitude of the antenna's geodetic location may require this limitation for the azimuth axis. With such a satellite, the elevation may move several degrees while the azimuth shows almost no motion.
- **CLRMEM** --- Clicking to this button clears the tracking memory. You should do this when you start to track a new satellite. Clearing the tracking memory about half an hour after tracking started significantly improves the quality of the first adaptive tracking model which will be evaluated after 6 hours of tracking. This is because the model does not get disturbed by the first search steps the antenna does until the optimal pointing to the satellite is found.

3.14.2.6 The Satellite Select Screen

The satellite select screen combines two functions for pointing the antenna to a satellite's position: The entry of ephemeris data to the pointing robot and the administration of the ACU's target memory locations.



The upper part of the screen is used to feed the pointing robot with the ephemeris data this requires to point the antenna to the satellite's position.

The usage is very simple: Copy the ephemeris data from e.g. your web browser window into the 'ephemeris data' field and click to the 'CALCULATE' button. The software tries to identify and parse the data and sets the informational fields on this right site to the values computed from the data. The 'azimuth' / 'elevation' / 'polarization' files show the antenna pointing which actually lets the antenna look to the satellite. The values below describe the type and the age of the ephemeris data set.

The pointing robot is capable interpret several types of ephemeris data including Keplerian elements in NASA 2-line format, Intelsat data, plain orbit positions and tables of az/el/pol value triples. The description of the Pointing-Robot logical devices describes the recognized data formats in detail.

The button 'GO' lets you make the pointing robot assist you in finding a satellite: Enter the satellite's nominal orbit position (or it's ephemeris data, if known), then click to 'CALCULATE', verify the calculated antenna pointing anf finally click the 'GO' to let the antenna move to this position.

The lower part of the screen manages the permanent storage of satellite parameters. Up to 24 satellites may be stored. The target memories store the antenna pointing and all tracking parameters. They are physically stored at the ODM's flash memory. If the ODM gets replaced, the stored positions are lost.

The ACU also stores the beacon receiver settings together with a target. These are stored at

the beacon receiver itself. The ODM, when receiving a command to store or recall a target memory, sends a command to beacon receiver to do the same.

- --- Recalls this preset. The antenna is moved to the stored position, all tracking parameter are set as stored and the beacon receiver's parameters are set from the values stored with the preset. The tracking memory is cleared if a target memory is recalled. Only if the target number 0 is recalled, the tracking memory is restored to the state when this target was saved.
- --- Stores the actual settings in this preset. The satellite name, the actual pointing and all tracking parameter are stored in the preset. The beacon receiver parameters are stored as well.
- --- The preset memory with this number is deleted.

The target memory location 0 is a special one. Unless the other memory locations, this first one stores the contents of the tracking memory and all temporary tracking data like models etc. together with the position and parameters.

This makes the first memory location dedicated to the short time storage of a satellites tracking state, when another satellite shall be tracked for a couple of hours. Example:

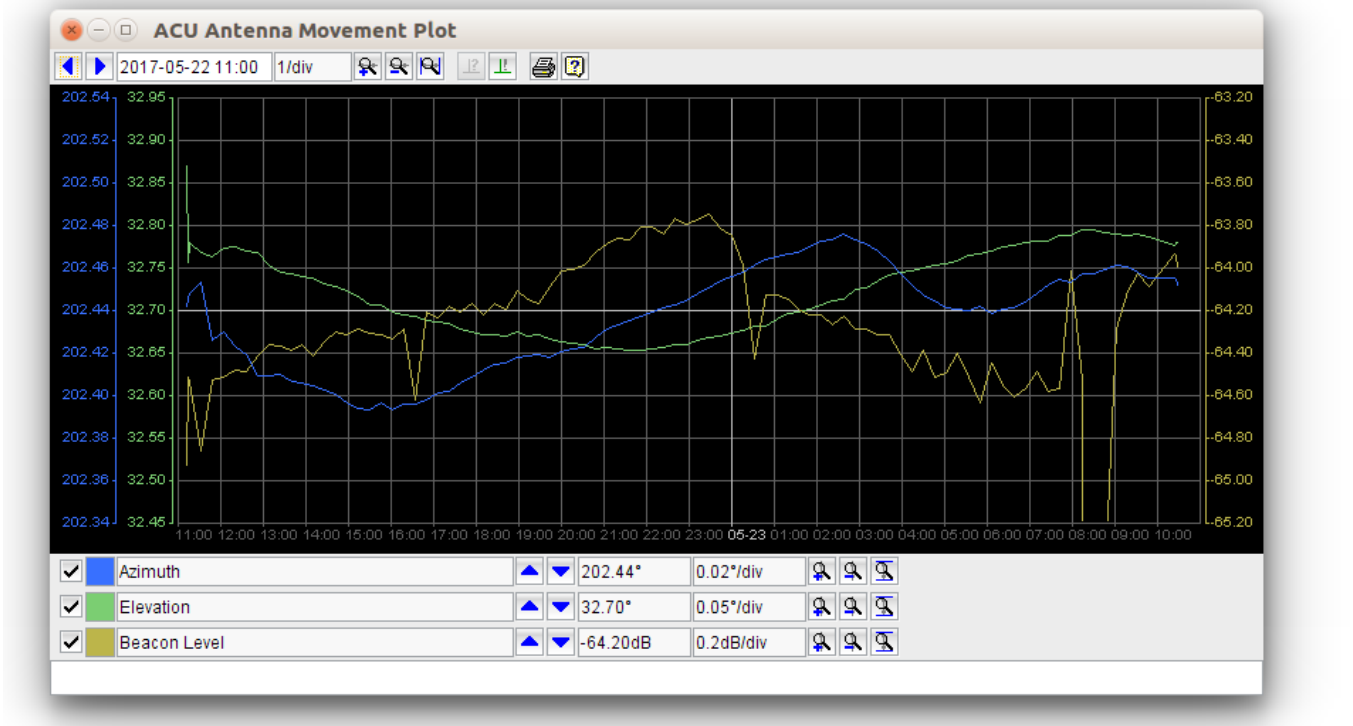
The antenna is tracking satellite A for a long time, the tracking memory is filled with 70 hours of step track data for this satellite. During a maintenance phase, the antenna shall temporarily track satellite B. With the target 0 memory you would handle this situation as follows:

1. Store the actual state as target 0 *before* the antenna is moved to point to satellite B.
2. Move the antenna to point to satellite B, either by recalling the target memory for this satellite or by pointing the antenna and clearing the tracking memory manually.
3. Let the antenna track satellite B for a couple of hours as needed.
4. No return to satellite A by recalling the target memory 0. This points the antenna back to satellite A and restores the tracking memory data for this satellite.

You should consider that it only makes sense to reuse the stored tracking data if there is less than twelve hours of discontinuity in tracking the satellite. If too much data is missing, clearing the tracking memory wil give the more reliable results.

3.14.2.7 The Y/T Tracking History Viewer

The sat-nms ACU IDU software provides a facility that permits to display the recorded tracking data in a versatile Y/T diagram viewer. This viewer may be launched by clicking to the "Y/T Plot" button either in the *ACU Main Screen* or in the device screen of the Satservice ACU-ODM.



The window shows a diagram of the recorded tracking data, the fields and buttons in the tool bar permit to modify the appearance of the diagram as needed. Clicking into the diagram shows a marker which displays a readout of the value at the selected screen position in the status bar at the bottom of the screen.

Top Toolbar

- --- Moves the plot two divisions to the left, lets you see older data.
- --- Moves the plot two divisions to the right, lets you see younger data.
- --- Shows/edits the start time. The displayed time corresponds to the leftmost grid line in the diagram.
- --- Zooms in the time scale, shows a smaller section of the data more detailed.
- --- Zooms out the time scale, shows a larger section of the data.
- --- Zooms out to show the recent 24 hours of recorded data.
- --- If pressed (it's a latching button), the search step beacon degradation is shown together with the beacon level. This function is not available with the SatService ACU-ODM.
- --- If pressed, the AZ/EL pointing determined by the peaking algorithm are shown as a second curve. The main curve shows the pointing angles where the antenna was moved to, including and optimization or smoothing applied.
- --- Prints the diagram as actually shown.

- --- Shows this manual page.

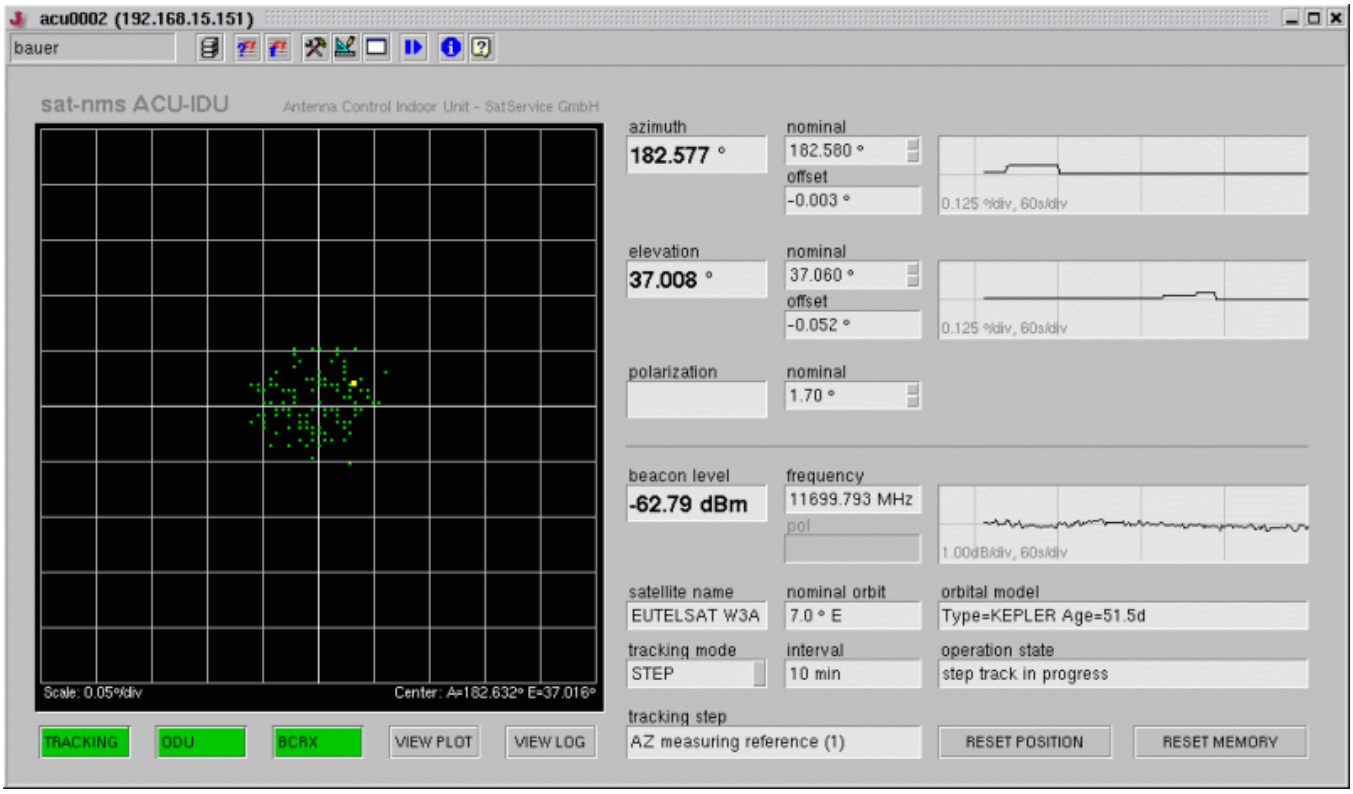
Bottom Toolbars

Below the diagram, the History File Viewer provides three toolbars to modify the scaling of the traces "Azimuth", "Elevation" and "Beacon Level" shown in the diagram.

- --- The first control in each toolbar selects if the trace shall be drawn.
- --- Shows the color if this trace, clicking to the color fields opens a dialog which lets you change the color of the trace.
- --- Shows the name / description of the trace.
- --- Moves the trace upwards one division.
- --- Moves the trace down one division
- --- Shows the y-scale reference level and the actual scaling. The y-reference level is the value corresponding to middle grid line.
- --- Zooms in the y-scale for this trace.
- --- Zooms out the y-scale for this trace.
- --- Zooms to show the min/max values (autoscale). This refers to the entire data, not only to the part actually shown.

3.14.3 The ACU Main Window (with 3rd party controller)

The main screen of the sat-nms ACU Indoor Unit shows the main parameters of the antenna tracking control similar to the front panel of a oscilloscope. The left part of the window contains a diagram which shows the antenna movements of the past 48 hours. The most important settings and status displays are located at the right.

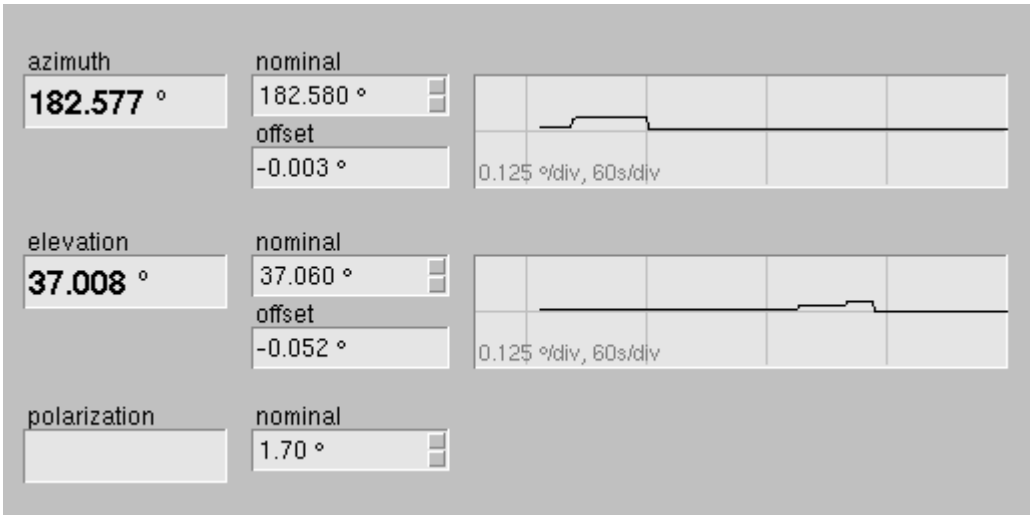


The toolbar on top of the window gives access to user login/logout, the event log and some other functions. As the ACU indoor unit inside principally is a M&C system, the toolbar is exactly the same as for the M&C Main Window .

At the top of the right part of the window thepointing display is located. It shows the actual antenna pointing and a strip chart of the recent history of antenna movements. Below the pointing display you find the beacon level display It reports the actual beacon level in a similar way. At the bottom of the right side the window contains an area with the tracking status display . Finally, below the tracking diagram on the left side, the ACU main screen contains the ACU subsystem menu . These five buttons give you access to subsystem screens with all detail parameters of the ACU / tracking.

3.14.3.1 The Pointing Display

The area in the upper right part of the window shows the actual antenna pointing and provides entry fields to move the antenna to a given position. The example below is taken from an antenna which is not equipped with a polarization motor, the polarization angle display is empty therefore.



The fields labeled 'azimuth', 'elevation' and 'polarization' show the actual antenna pointing as read out from the angle encoders. For azimuth and elevation there is also a strip chart display of the angle. If you choose a high resolution scale for the chart, you can watch the antenna doing the tracking steps in the chart. Click with the right mouse button into the chart to get a pop-up menu for scales and other display options.

The 'nominal' fields define the nominal antenna pointing for the actual satellite. The nominal pointing describes the center of the satellite's path over 24 hours.

- If you store the antenna pointing and the tracking parameters as a ACU preset, the software stores the nominal pointing. If you recall the preset, the software moves the antenna to the stored pointing and starts tracking there in the operation mode stored with the preset.
- The antenna moves to the nominal position, if you click to the 'RESET POSITION' button.
- The absolute tracking limits configured in the TRACKING subsystem refer to the nominal antenna pointing.

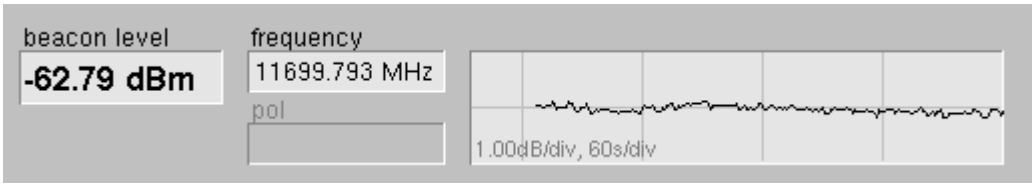
If you change a nominal pointing value while the antenna has tracking switched on, this only moves the reference point for the tracking limits. The antenna is under control of the tracking engine and does not move due to this change.

If the ACU tracking mode is set OFF, the antenna behaves differently. In this case changes of the nominal value let the antenna move immediately to the selected position.

Finally, the 'offset' fields indicate the actual difference between the real antenna pointing and the nominal position.

3.14.3.2 The Beacon Level Display

Below the antenna pointing, the ACU shows the actual beacon level. There is also a strip chart display of the level. The chart moves with the same speed as the angle charts above, so you directly can watch the influence of tracking steps to the beacon level. A click with the right mouse button into the chart shows a pop-up menu for scales and other display options.

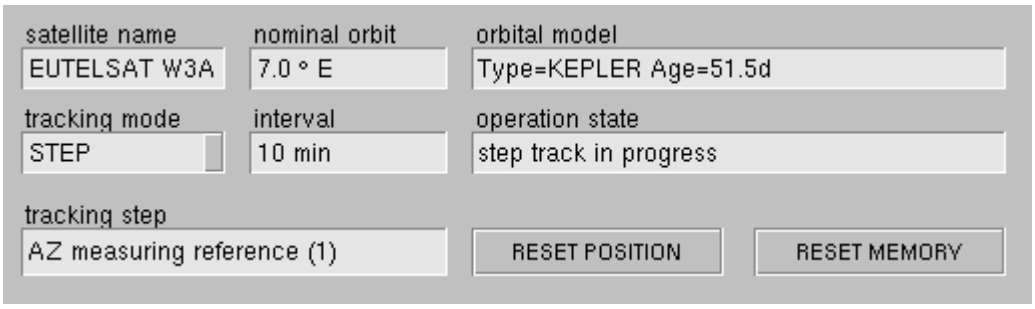


The screen also provides fields to set the beacon frequency and the receive polarization (the latter is not supported by antenna where the example picture has been taken from). Changing the values in these fields changes the beacon receiver setting immediately.

If you are using a third party beacon receiver which is not controlled by the ACU indoor unit, you nevertheless have to set the beacon frequency here. This is because the tracking software takes the frequency into account when estimating the antenna receive pattern and from this the tracing step sizes.

3.14.3.3 The Tracking Status Display

The lower right area of the ACU main window shows the tracking status display and the basic tracking mode parameters.



The table below gives a short description of each parameter in this area. The all refer to the TRACKING subsystem , this chapter gives a more detailed description of the tracking.

- **satellite name** --- The name of the satellite you are tracking.
- **nominal orbit** --- The nominal orbit position of the satellite.
- **orbital model** --- The type and age of the orbital model the ACU uses for the PROGRAM track mode. During ADAPTIVE tracking, the the number of hours in memory are displayed here.
- **tracking mode** --- With this parameter you set the basic tracking mode. Available modes are OFF, STEP, ADAPTIVE and PROGRAM..te .ts **interval**With this parameter you define in which intervals the ACU shall perform tracking steps.
- **operation state** --- This field shows the general operation state of the tracking engine.
- **tracking step** --- This field tells what the tracking engine is doing actually in this moment.
- **RESET POSITION** --- Moves the antenna back to the nominal pointing values. If you do this in ADAPTIVE or in PROGRAM track mode, the antenna will return to the estimated pointing with the next tracking step. With STEP track mode, the antenna starts tracking at the nominal pointing if you click to this button
- **RESET MEMORY** --- Clicking to this button clears the tracking memory, the ACU

remembers to estimate the antenna pointing in ADAPTIVE mode. You should do this if you change tracking to another satellite or if you recognize a significant repositioning of the satellite.

3.14.3.4 The ACU Subsystem Menu

The five icons below the tracking diagram are the ACU subsystem menu. Although looking unimposing, this menu is very important as it gives you access to all parameters of the ACU's subsystems.

Clicking to the TRACKING icon launches a window which shows all parameters of the tracking subsystem. The color of the icon tells about the fault state of the tracking engine (green = OK, red = FAULT). You open the TRACKING subsystem window in order to

- save and recall satellite presets.
- adapt low level tracking parameters like step sizes, averaging times etc.
- enter ephemeris data for antenna positioning or PROGRAM track mode.

The ODU icon opens a window to operate / configure the antenna positioner device. Normally it will not be necessary to access the positioner directly in this ACU configuration, moreover, it might mess up the tracking process if you command the antenna directly. There are however a few situations where you want to see all antenna parameters:

- The positioner shows a fault (red icon) and you want to know what the reason for the fault is.
- You want to move the antenna manually in small steps, e.g for the pointing calibration or for measurements. The SatService ACU ODM device window provides step movement buttons which help you to do this efficiently.

The BCRX icon opens a window directly to operate / configure the beacon receiver attached to the ACU. This window is required to set other beacon receiver parameter than the frequency or receive polarization.

The 'VIEW PLOT' button opens a separate graphical Y/T display window which gives more detailed information about what the tracking engine did during the recorded 48 hours. It provides variable scales, and permits to display additional information. The display shows either the azimuth or the elevation pointing found at the beginning of each tracking step together with the beacon level measured at this time. The following additional information may be included to the diagram:

- --- If this toolbar button is pressed, the diagram shows the search step and the beacon level change resulting from this as a dimmed peak at the left edge of each data point. You can easily monitor the signal degradation which is caused temporarily by the tracking search steps with this function enabled.
- --- If this toolbar button is pressed, the diagram includes the evaluated peak positions.

In STEP track mode, this actually is the location where the antenna gets moved to. In ADAPTIVE tracking mode, the antenna moves to the location resulting from the mathematical model which is computed from the step track peaks. In the latter case, the peak positions may be interpreted as the actual difference between the modeled pointing and the peak position.

Clicking to the 'VIEW LOG' button opens a window where the program shows a live report what the tracking engine actually is doing. The log in this window is cleared with each new tracking step. If 'Y/T PLOT' diagram shows many unsuccessful tracking steps, watching the log reports may give an explanation why the tracking engine discards so many steps.

3.15 Specialized Client Applications

In addition to the standard Java client, the sat-nms software provides a number of client applications specialized to certain tasks. This chapter describes the operation of these (legacy) appliacations. Thy are:

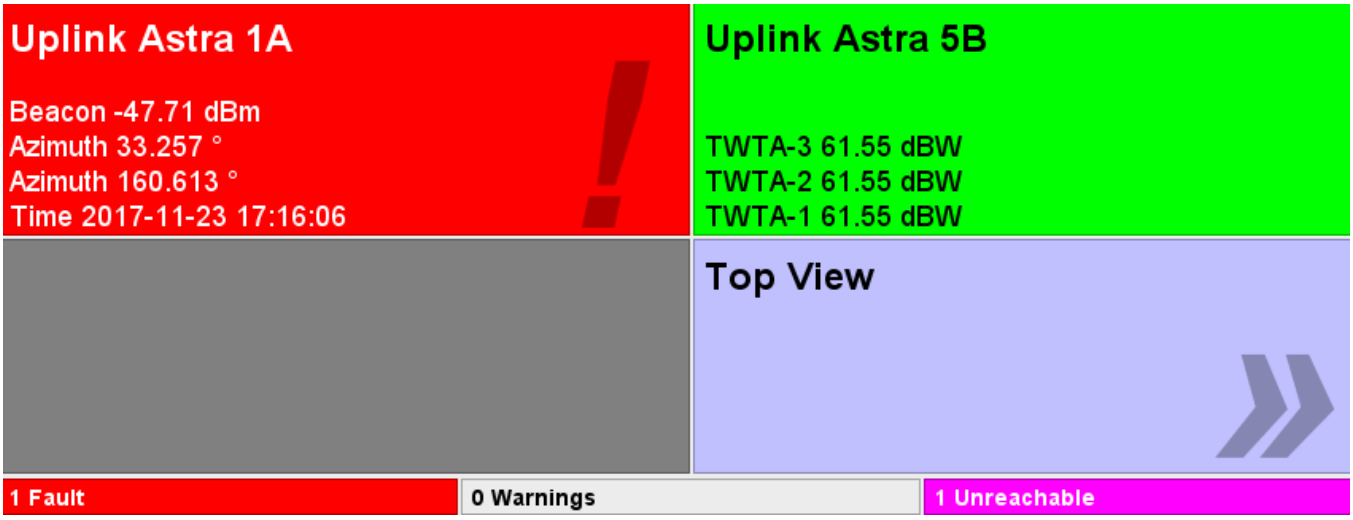
- The MasterClient Application The sat-nms MasterClient-2 is a client program for multiple sat-nms M&C servers. It can be used in parallel to the standard M&C client program in order to organise certain M&C system under a common main GUI.
- The ServiceClient Application The sat-nms Service-Client is a client program for the sat-nms M&C server. It can be used in parallel to the standard M&C client program in order to organise certain devices and device parameters in "services".
- The ViOIPClient Application The sat-nms VioIP (video over IP) Software is an extension to the sat-nms M&C software which permits to manage video over IP transmissions in a given IP network. The software manages resources like the bandwidth of connections between two nodes of the network or the usage of endpoint devices.
- The VioIP Network Configuration Application This program permits to add or delete locations, endpoint devices or data lines between the locations.

3.15.1 Master Client 2

The sat-nms MasterClient-2 is a client program for multiple sat-nms M&C servers. It can be used in parallel to the standard M&C client program in order to organise certain M&C system under a common main GUI.

You can invoke the MasterClient 2 with the following instructions (e.g. in a shortcut):

javaw -cp client.jar satnms3.mc2.MasterClient [config-file-name].xml



3.15.1.1 MasterClient 2 XML Configuration File

The version 2 MasterClient program reads it's configuration an XML file. Structure and the meaning of the XML elements are described in the following chapters.

When the MasteClient program is started without a command line argument, it reads a file **MasterClient.xml** in the actual working directory to read its configuration Alternatively a file or path name may be given as the only command line argument, the program then will read this file instead.

XML Element Hierarchy

The diagram below shows the overall tree structure of the XML elements making up the MasterClient's configuration. Most elements may appear multiple times except the <masterclient> element.

```
<masterclient>         The root element
|
+-<global>            Definition of a global parameter
|
+-<peerlist>          List of all peers to M&C systems
| |
| +-<peer>            Definition of one peer to a M&C system
|   |
|   +-<parameter>       Definition of an optional parameter to be
|                   watched at the M&C
|
+-<grouplist>          List of all groups
| |
| +-<group>           Definition of one group
|   |
|   +-<member>         Definition of one member in the group
|
+-<screenlist>         List of all screens
  |
  +-<screen>           Definition of one screen
    |
    +-<row>           Definition of one row of buttons in this screen
      |
      +-<button>       Definition of one button
```

3.15.1.2 XML Element Description

The following paragraphs describe each element which may occur in the configuration file with its possible children and attributes.

- <masterclient> --- The **<masterclient>** element is the root element of the XML tree. It contains all elements which make up the the master client's configuration. Elements outside the **<masterclient>** element are ignored.
- <global> --- The **<masterclient>** element may contain zero or more **<global>** elements. These elements define global settings of the master client program. They don't have child elements but they each have two attributes which both are mandatory: *key* and *value* .The following keys are defined:
  - fontSize --- The size (pixels) of the font used for the button labels.
  - fontSizeParam --- The size (pixels) of the font used for parameters in M&C buttons.
  - title --- The text to shown in the window title bar
  - okColor --- The color of a button standing for a M&C or group which is in state *OK* .
  - faultColor --- The color of a button standing for a M&C or group which is in state *FAULT* .
  - warningColor --- The color of a button standing for a M&C or group which is in state *WARNING* .
  - linkColor --- The color of a button which simply changes to another screen without

showing a fault state
- unreachableColor --- The color of a button standing for a M&C or group which is in state *UNREACHABLE* .
- disabledColor --- The color of a button standing for a M&C or group which is actually disabled.
- autoTextColor --- One of *true* or *false* . With *true* the button text is drawn black bright background colors, white for dark background colors for better contrast. With *false* the text is always drawn black.
- showSymbols --- One of *true* or *false* . If set *true* , the state of a M&C or group button is not only symbolized by its color but also by an exclamation mark for *FAULT/WARNING* or a question mark for *UNREACHABLE* . These symbols are drawn large in a faded color as part of the button background.
- priorityScheme --- One of *FAULT* or *UNREACHABLE* . Defines the priority of states a group uses to combine the states of its children. When set to *FAULT* , the priority is FAULT (highest) - WARNING - UNREACHABLE - OK (lowest).When set to *UNREACHABLE* the priority is UNREACHABLE (highest) - FAULT - WARNING - OK (lowest).A group always shows the highest priorized state one of its children shows.

Examples and default values for all keys:

```
<global key="fontSize" value="14" />
<global key="title" value="sat-nms Master Client 2" />
<global key="okColor" value="#00FF00" />
<global key="faultColor" value="#FF0000" />
<global key="warningColor" value="#FFFF00" />
<global key="linkColor" value="#8080FF" />
<global key="unreachableColor" value="#808080" />
<global key="disabledColor" value="#808080" />
<global key="autoTextColor" value="true" />
<global key="showSymbols" value="true" />
<global key="priorityScheme" value="FAULT" />
```

- <peerlist> --- The <peerlist> element contains the definition of all peers, each connecting to one M&C system and watching its state.
- <peer> --- The **<peer>** element defines one peer connecting to a M&C system and watching its state. The **<peer>** element may contain zero or more **<parameter>** elements which define parameters to watch additionally to the M&C summary fault state.Each **<peer>** element has a number of attributes which identify the element and define how to connect to the M&C system:
  - id --- A unique name identifying this peer. Groups and screen buttons use this identifier to refer to this peer / M&C. This attribute is mandatory.
  - ip --- The IP address of the M&C in dotted quad notation. This attribute is mandatory.
  - mode --- One of *enabled* or *disabled* This defines the the initial mode of this peer after program start. Enables peers operate normally and reflect their fault state as reported by the M&C. Disabled peers show a state *disabled* regardless of the fault state of the M&C. The mode attribute is optional, the program assumes *enabled* if

the attribute is missing.
    - clientpars --- Optional parameters added to the command line which launches the client program when the operator clicks to a button referring to this M&C. Typical contents for the clientpars attribute are user/password settings.

Examples:

```
<peer id="MNC1" ip="192.168.0.100" clientpars="-u satnms -p satnms -s default -q" />
<peer id="MNC2" ip="192.168.0.101" clientpars="-u satnms -p satnms -s default -q">
   <parameter id="EIRP-2.on" label="TX" />
</peer>
```

- <parameter> --- The **<parameter>** element defines one parameter the peer shall watch at its M&C additionally to the summary fault. A **<peer>** element may contain an arbitrary number of **<parameter>** elements as children.A screen button referring to the peer shows the actual values of the defined parameters, starting with the first parameter near the bottom of the button rectangle, the second one above this and so on.Parameters are shown with a fixed font size, depending on the button size they may be covered by the button label or completely ourside the button area, invisible for this reason.A **<parameter>** element contains these two attributes:
    - id --- The message ID of the parameter to watch.
    - label --- A label drawn on the screen button left of the parameter value

Example:

```
<parameter id="SYSTEM.time" label="Time" />
```

- <grouplist> --- The **<grouplist>** element contains the definition of all groups.
- <group> --- The **<group>** element defines one group within the **<grouplist>** . The group is named by a identifier, the group members are defined by **<member>** child elements within the **<group>** . The **<group>** element knows one (mandatory) attribute:
    - id --- A unique name identifying this group. Other groups and screen buttons use this identifier to refer to this group. Identifiers must be unique across **<peers>** and **<groups>** because both may appear as group members and state sources for screen buttons in the same way.

Example

```
<group id="GRP1">
  <member id="MNC1" />
 <member id="MNC2" />
</group>
```

- <member> --- The **<member>** element defines one group member within a **<group>** definition. The **<member>** element has one mandatory attribute selecting the **<peer>** or **<group>** as the group member:
    - id --- The existing name / identifier of the peer or group which shall be a member of

this group.

Example:

```
<member id="MNC1" />
```

When defining group members, care should be taken not to create circular references between groups: if e.g. a group defines itself als member or group A has group B as member and at the same time group B defines group A as member, this creates a race condition in the software, the master client won't work.

- <screenlist> --- The **<screenlist>** element contains the definition of all screens. The **<screenlist>** element may contain one attribute:
  - default --- The ID of the screen which shall be loaded when the program

Example:

```
<screenlist default="HOME">  ...  </screenlist>
```

- <screen> --- The **<screen>** element defines one screen of the MasterClient program. The MasterClient always shows one grid of N x M buttons. A screen is one set of such buttons shown at a time. Buttons referring to groups or simple link buttons may be clicked to switch to another screen, another set of buttons.A screen is defines as a sequence of **<row>** elements each containing a sequence or **<button>** elements. Buttons appear from left to right in a row, rows appear from top to bottom in the screen. The program scans the screen definitions at startup and evaluates the maximum number of rows and columns defined. The MasterClient always shows a grid of this size, filling it up with empty buttons if a particular screen or row is smaller than the evaluated size.The **<screen>** element contain one mandatory attribute:
  - id --- A unique name identifying this screen. The default attribute of the **<screenlist>** element and the **<target>** attribute of the **<button>** element refer to this identifiers to select this screen.

Example:

```
<screen id="HOME">  ...  </screen>
```

- <row> --- The **<row>** element defines one row of buttons in the screen. It has no attributes, contains zero or more **<button>** elements.
- <button> --- The **<button>** element defines one button within the row / screen. It contains up to three attributes:
  - src
  - label
  - target

Depending on the presence of attributes a button behaves differently

- A button without any attributes behaves as a dummy button or spacer

- A button containing a *target* attribute but no *src* attribute behaves as a link button, it simply switches to the target screen when clicked
- A button containing a *src* attribute referring to a **<peer>** element is a M&C button. It shows the fault state of the M&C and launches the client program for this M&C when clicked. It should not contain a *target* attribute.
- A button containing a *src* attribute referring to a **<group>** element is a group button. It shows the fault state combined by this group It must contain a *target* attribute which denotes the screen to be shown when the button is clicked.

3.15.1.3 Example showing a complete screenlist

```
<screenlist default="HOME">
 <screen id="HOME">
  <row>
   <button src="GRP1" label="Group 1" target="G1SCREEN" />
   <button src="GRP2" label="Group 2" target="G2SCREEN" />
  </row>
 </screen>
 <screen id="G1SCREEN">
  <row>
   <button src="MNC1" label="Station A" />
   <button src="MNC2" label="Station B" />
  </row>
  <row>
   <button />
   <button target="HOME" label="Top View" />
  </row>
 </screen>
 <screen id="G2SCREEN">
  <row>
   <button src="MNC3" label="Station C" />
   <button src="MNC4" label="Station D" />
  </row>
  <row>
   <button />
   <button target="HOME" label="Top View"/>
  </row>
 </screen>
</screenlist>
```

3.15.2 Service Client Application

The sat-nms Service-Client is a client program for the sat-nms M&C server. It can be used in parallel to the standard M&C client program in order to organise certain devices and device parameters in "services".

There may be multiple instances of the Service-Client running at the the same time. Operating

the software is fully multi-user capable, but adding/removing services should be done only from one computer at a time.

Service Definition A service is a combination of an arbitrary number of properties which each may be a up- or down converter, a splitter output, a combiner input, a fibre output or a test port. For each type of property there is a number of parameters which are monitored and - if applicable - controlled.

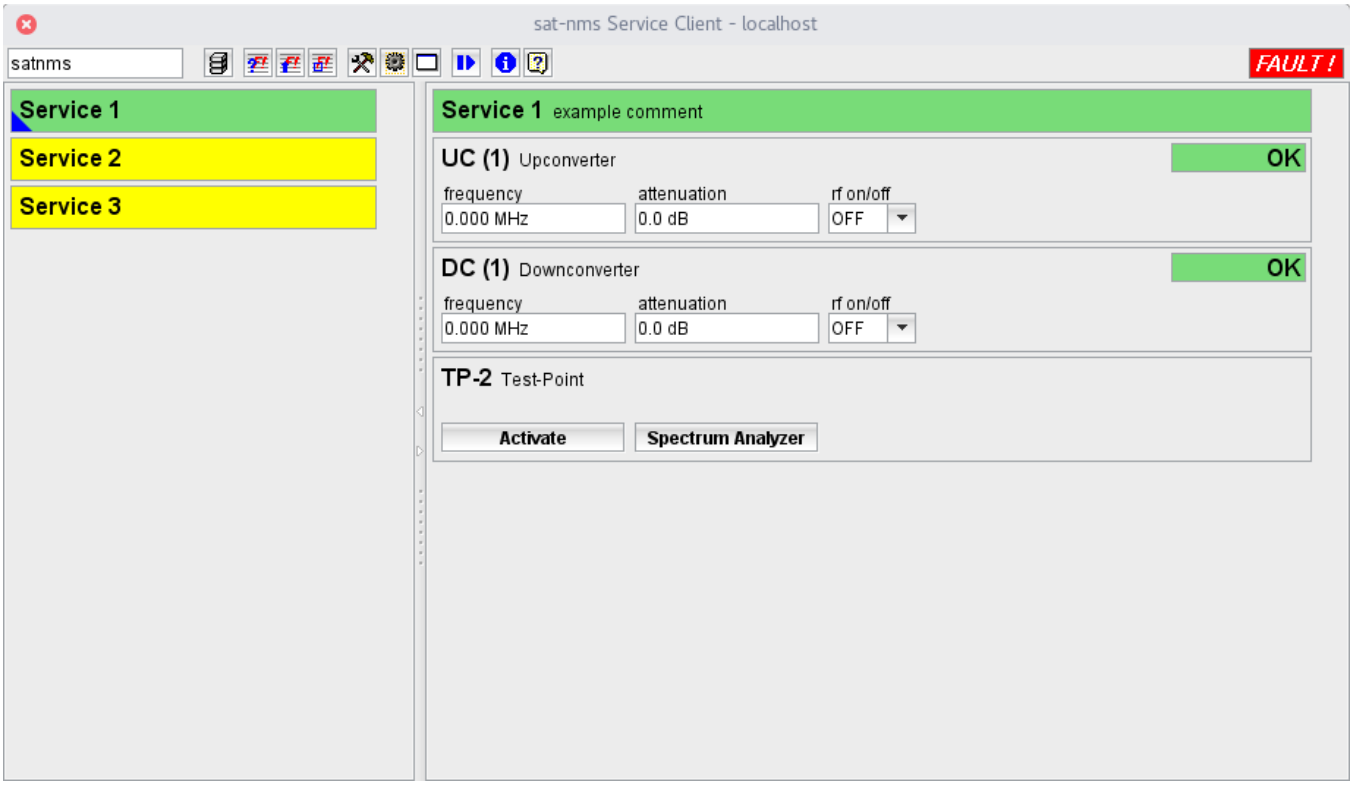
- property type --- monitoring only parameters, m&c parameters
- up-/downconverter --- fault flagfrequency attenuation signal on/off
- splitter output --- fault flag measured level (may be the common level at the splitter input)port on/off
- combiner input --- fault flag measured levelport on/off
- fibre output --- fault flag
- test output --- button/command to set all switch positions required to route the service output signal to this test point

There is a summary fault state for each service which is the "worst condition" of the properties contained in this service. This service summary fault states does not appear in the server's event log as it is evaluated in the client program and known only there.

Operation

The Service-Client window mainly consists of a list of available services at the left and the actual settings / readings of the selected service at the right. By clicking to a service name the service gets selected and its parameters are shown at the right. Both, service list and parameter panel automatically add vertical scrollbars if required.

The program inherits a lot of functions from the sat-nms standard M&C client. It uses the same login scheme as the standard M&C GUI, toolbar buttons for event report query, live event log and list of active faults work in the same way here.



At the left side the window shows a list of all defined services. The background color shows the actual fault state of the particular service (one of DISABLED/OK/WARNING/FAULT). The colors used for this are configurable. Clicking with the right mouse button on a service name opens a context menu at the mouse pointer containing some convenience functions like enabling/disabling the service summary fault or opening the configuration editor for this service. The service fault status is updated in near real time for all defined service which are not "disabled".

The right side of the window shows the parameters and state of the actually selected service. For each property belonging to the service, a field containing the property's name, parameters and fault state. The layout of these fields is defined by a XML configuration file supplied by SarService. The displayed name of a property consists of a label for the property type, the sat-nms device name referenced and - if applicable - an index identifying the unit within the device used for this service.

Status values and control parameters of the properties of the selected service are updated in near real time like with the standard M&C GUI. Control parameters can be changed in place without the need to open another window.

Tool Bar

The Service Client provides a toolbar at the top of the window which gives access to a number of global functions in the software. Below there is a short description for each of the toolbar buttons.

- --- The left field at the window's tool-bar shows the login-name of the user who is

actually logged in. You may click with the mouse to this field, the program pops up the login/logout dialog.

- --- Shows a drop down list with all devices installed in the M&C system. Selecting a device from this list opens it's Device window .
- --- Opens the Event Report window .
- --- Opens the Live Event Log window .
- --- Opens a list of currently active faults.
- --- Opens the Device Setup window to configure the device setup of the M&C system.
- --- Switches the service client window to "edit" mode, lets you add or delete services or change service definitions (see "Configuration" below)
- --- Opens a terminal window which connects to the debug / test port of the M&C server.
- --- Opens the Macro Management window which controls recording and replay of equipment setting macros.
- --- Shows the program version info.
- --- Shows this help page.

Configuration

Configuring the Service-Client means to add or remove equipment (properties) from an existing service definition or to add or remove complete service definitions. For this purpose the Service-Client provides a configuration mode which can be switched on from the main window's tool bar. The configuration mode permits to:

- Add a new service
- Delete an existing service
- Change the order in which the services appear in the GUI
- Change the name of an existing service
- Add a property to an existing service
- Remove a property from an existing service
- Change the order in which the properties appear in the GUI

Changes made in configuration mode are reflected immediately, e.g. an added property shows up as soon as it is added. There is no "save" button in the configuration mode, all changes which are made are permanent.

When the configuration of services is changed, all other opened service clients are informed to re-read the configuration from the server to get updated. This happens within 15 seconds after a configuration change has been made.

When adding a new property to a service, the software knows which sat-nms devices or units within devices are suitable for the selected purpose. The software also knows which properties may be used only once and cannot configured a second time.

The operator gets a list of actually possible devices which may be configured as the new property for the service and selects the hardware representation of the property from this list.

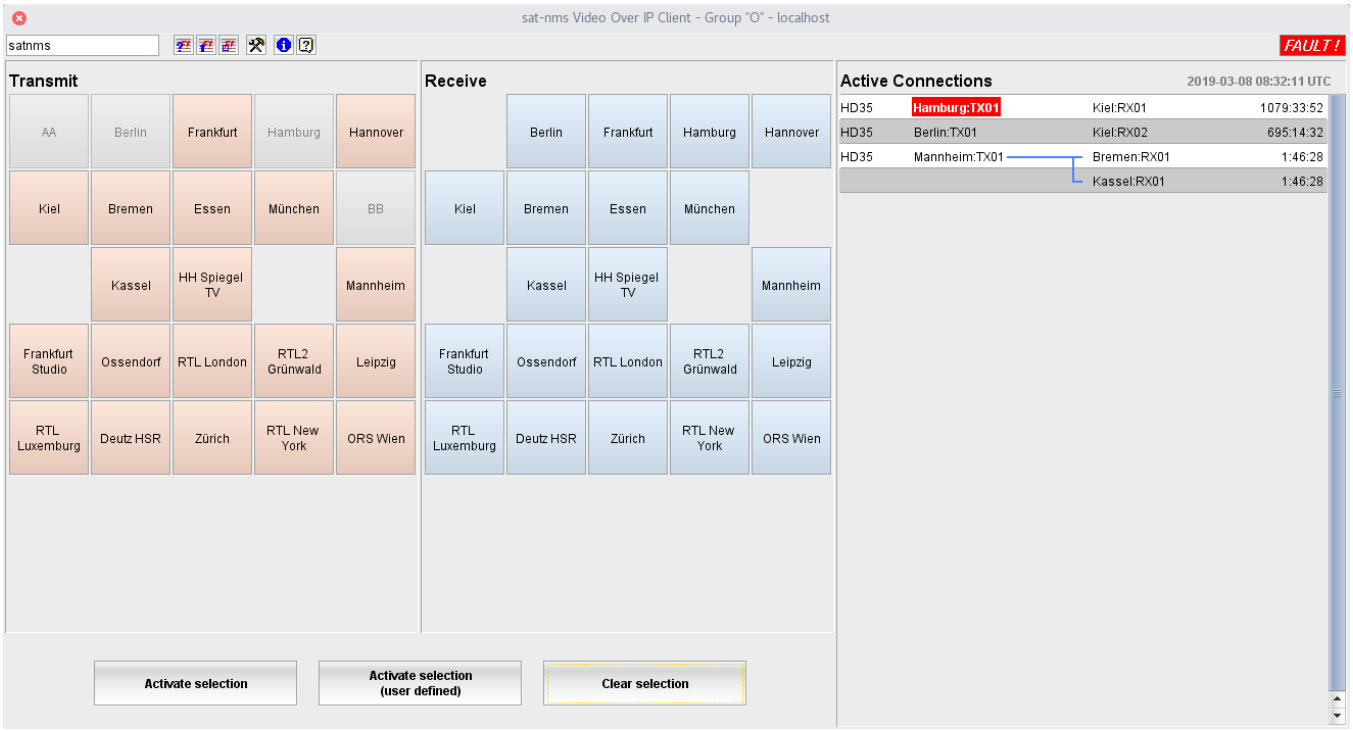
The knowledge, which types of devices are suitable e.g. as a combiner input, how many identical units of this a sat-nms device manages and through which parameter identifiers the

desired combiner port is addressed is defined in an XML configuration file which is supplied by SatService. By editing this file, more / new device types may be added to the list of known device drivers for the software.

3.15.3 VioIP Client Application

The sat-nms VioIP (video over IP) Software is an extension to the sat-nms M&C software which permits to manage video over IP transmissions in a given IP network. The software manages resources like the bandwidth of connections between two nodes of the network or the usage of endpoint devices.

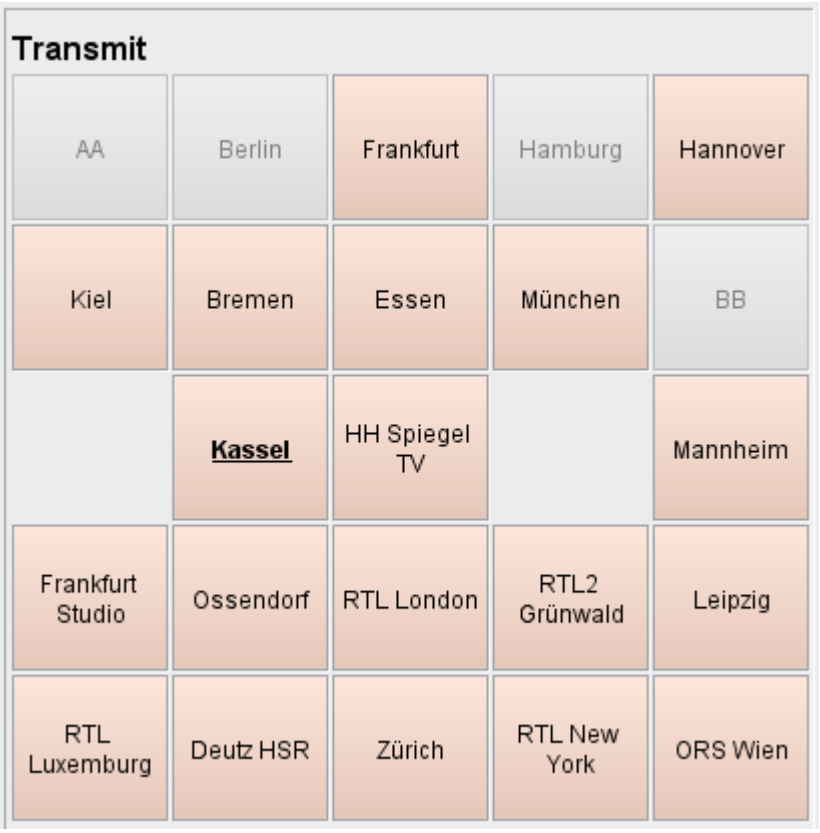
The sat-nms VioIP Software consists of an extension to the sat-nms M&C server with the resource database, the VioIP Client Application which is used to start or stop transmissions and finally the VioIP Network Configuration Application which permits to add or delete locations, endpoint devices or data lines between the locations. The following paragraphs describe the VioIP Client Application.



The VioIP Client Application window consists of three major parts: The TX location button array, the RX location button array and the list of active connections. At the top of the window there is a tool bar giving access to some global functions of the sat-nms software.

TX location button array

The array of TX locations shows one button for each location defined in the software which has at least one TX end point device configured. The button array is used to select the source of a connection to be started.



If there are no devices available to start a new connection from a particular location (because all devices are either in use, temporarily disabled or in communication fault state), the button is grayed out and cannot be pressed.

To select a location simply click the button. The name of the selected location prints bold/underlined to signal that this location is selected as the source for the connection to be started next. Only one TX location may be selected at a time, to change the selected TX location simply click another one. The selection mark then moves to this location. To unselect a location, click the selected location again or click the "Cancel selection" button below the button arrays.

RX location button array

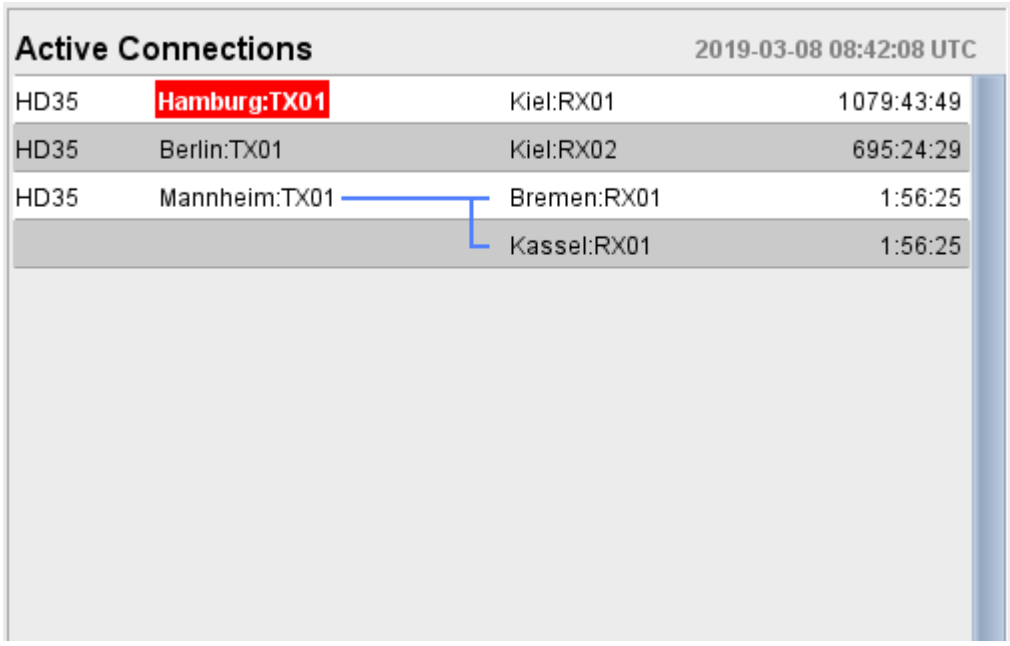
The array of RX locations shows one button for each location defined in the software which has at least one RX end point device configured. The button array is used to select the destination(s) of a connection to be started.

If there are no devices available to start a new connection to a particular location (because all devices are either in use, temporarily disabled or in communication fault state), the button is grayed out and cannot be pressed.

Using the RX location buttons is much like for the TX side, however the RX button array lets you multiple destination. Selecting more than one destination for an upcoming connection switches the operating mode to "multicast" which will send the program from the source location to all selected destinations.

Active connection list

The active connection list shows all active connection as a scrollable list, one connection per line. For each connection the video profile, the source (location and device) and the destination of the connection are shown. The last column shows the time how long this connection already is active.



Multicast groups are symbolized with blue lines, connecting one source to one or more destinations. If an end point device shows a fault while the connection is active, the name of the end point is drawn as white text on red background. Please note, that not all faults of the device are signalled in this way. In the logical VioIP-End-Point Device the faults are defined which are to be monitored while the connection is running.

Beside as a status display, the Active Connections list is used to protect, to un-protect and to stop running connections. Clicking with the right mouse button on a connection in the list shows a context menu which gives you several options, depending on the actual state of the connection. Below on this page you find paragraphs which describe elaborately how to terminate, protect or un-protect connections.

Tool bar buttons

The VioIP Client provides a toolbar at the top of the window which gives access to a number of global functions in the software. Below there is a short description for each of the toolbar buttons.

- --- The left field at the window's tool-bar shows the login-name of the user who is actually logged in. You may click with the mouse to this field, the program pops up the login/logout dialog.
- --- Opens the Event Report window .
- --- Opens the Live Event Log window .
- --- Opens a list of currently active faults.
- --- Opens the VioIP Network Configuration Application . This application lets you add or remove locations, end points, data lines an more. You must be logged as a user with privilege level 150 to use this function.
- --- Shows the program version info.
- --- Shows this help page.

Starting a connection

Starting a connection is straight forward, using the "Location Buttons" of the GUI. Click to a TX location and then to a RX location, finally click the "Activate selection" button below and the software starts a unicast connection between these locations. It uses the first available end point device at either location and the default video profile (bandwidth) for this.

You may select multiple RX locations by clicking the buttons in the RX location button array. In this case the software automatically uses multicast to transmit the program from the TX location simultaneously to all selected destinations.

If you accidentally selected an RX location, click it again to deselect it. This must be done before you activate the selection.

Terminating a connection

To terminate a connection click to the connection in the list with the right mouse button and select "Stop this connection" from the context menu popping up. With multicast connections there is also an option "Stop all connections of this multicast group".

Stopping a unicast connection means to turn off the transmission, switching all devices to stand-by and finally freeing the resources occupied by this connection (endpoint devices and used bandwidth). The same applies when stopping all connections of a multicast group or when stopping the very last connection of a multicast group.

Stopping a single connection from a multicast group means - unless this is the very last connection of this group which is still running - to switch of the receiver, freeing this as a resource and freeing the bandwidth which was used to send the signal to particularly this receiver.

Protecting a connection

Running connections may be protected from accidentally being terminated. Protected connections cannot be terminated directly, the protection must be removed before the connection can be terminated. Protected connections appear with a yellow colored background in the connection list.

To protect a connection, click to the connection in the list with the right mouse button and select "Protect this connection" from the context menu popping up. With multicast connections there is also an option "Protect all connections of this multicast group"

To remove the protection from a connection, click to the protected connection in the list with the right mouse button and select "Unprotect this connection" from the context menu popping up. With multicast connections there is also an option "Unprotect all connections of this multicast group"

Specifying end point devices explicitly

When starting a connection as described above, the software automatically selects the first available end point device at the selected location. You can explicitly specify the end point

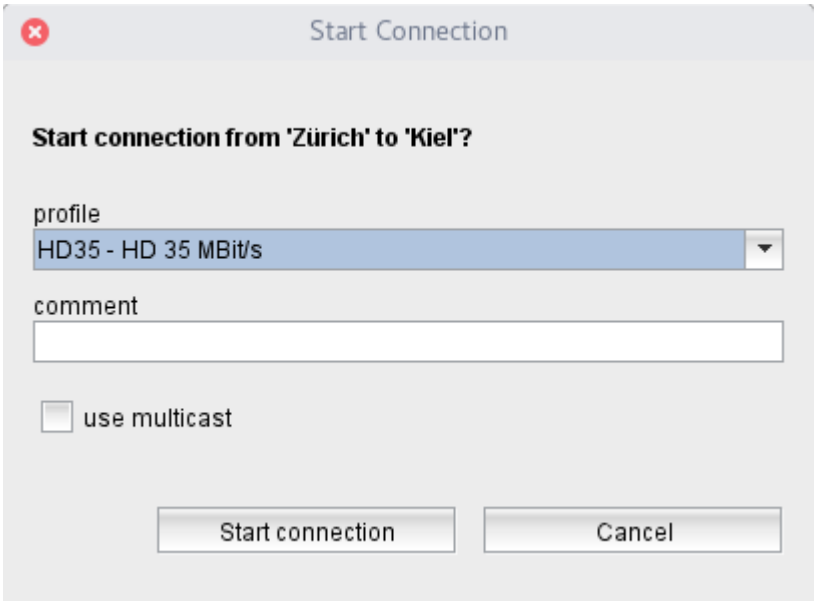
device to be used for a connection.

For this instead of left-clicking the location button use the right mouse button to show the context menu of the location button. Select the end point device of your choice from this menu.

Using a non-standard video profile / data rate

Connection which are established with the button "Activate selection" all use the default video profile and the bandwidth associated with this profile. The default profile is the first profile in the list of video profiles.

Using the button "Activate selection (user defined)" instead opens a dialog which lets you select a video profile from a list. This dialog also permits to set the "comment" property of a connection directly when the connection gets started.



Starting a multicast connection to a single destination

Using the "Activate selection (user defined)" button and the dialog window appearing with a click to this button, you may also start a connection to a single destination in multicast mode. To do this, set the check mark "use multicast" before clicking "Start connection".

Other functions

You may check the route, the software calculates for connections between two locations: Select a source location in the TX button array and then right-click the destination in the RX button array and select "Show route to here". The program displays a pop up window with the route.

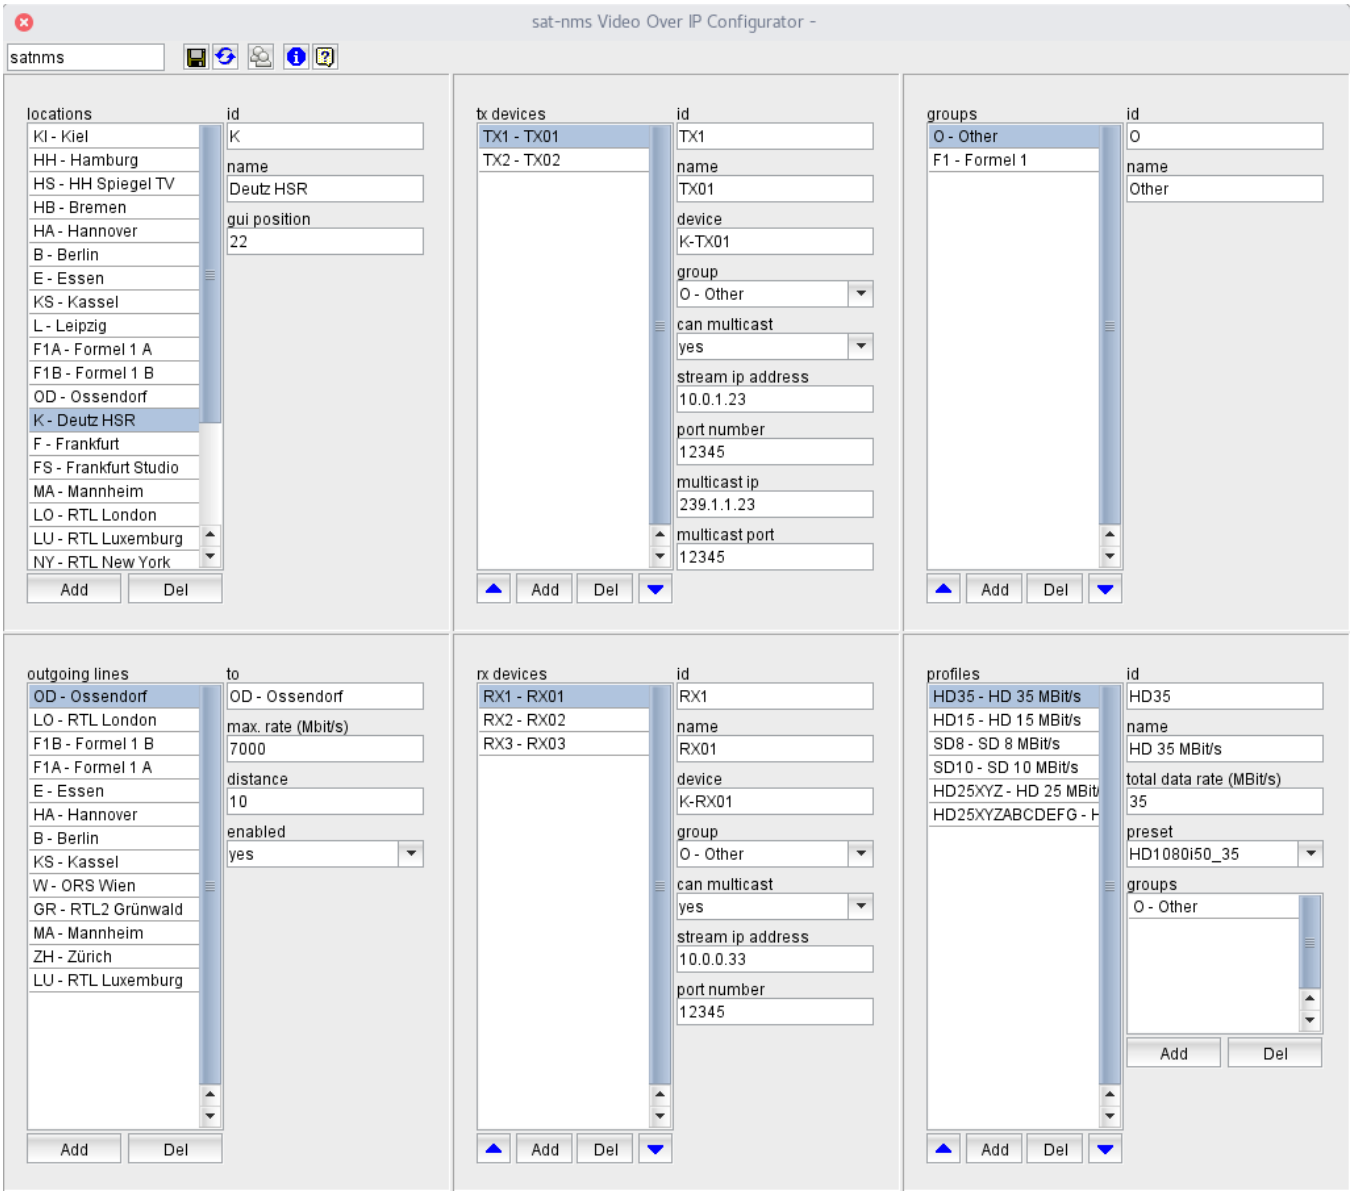
You may check the devices and outgoing lines for a location: Right-click the location button and select "Show location properties". The program displays a pop up window with requested information.

3.15.4 VioIP Network Configuration Application

The VioIP Network Configuration Application lets you configure many aspects of the VioIP Network. You can add or delete locations, endpoint devices or data lines between the locations.

The application works as a document editor: when started, it reads the actual VioIP network configuration and shows the settings. Edited settings are applied when the configuration is saved by clicking the "save" button in the tool bar. At any time you can revert the configuration to the settings which are actually running, e.g. if you deleted accidentally a location which shall not be deleted.

When you save an edited configuration, the program informs all running instances of the VioIP Client Application to reload the configuration in order to reflect the changes immediately. This is done unless you added or removed devices, in this case a restart of the M&C server is necessary to make the changes effective.



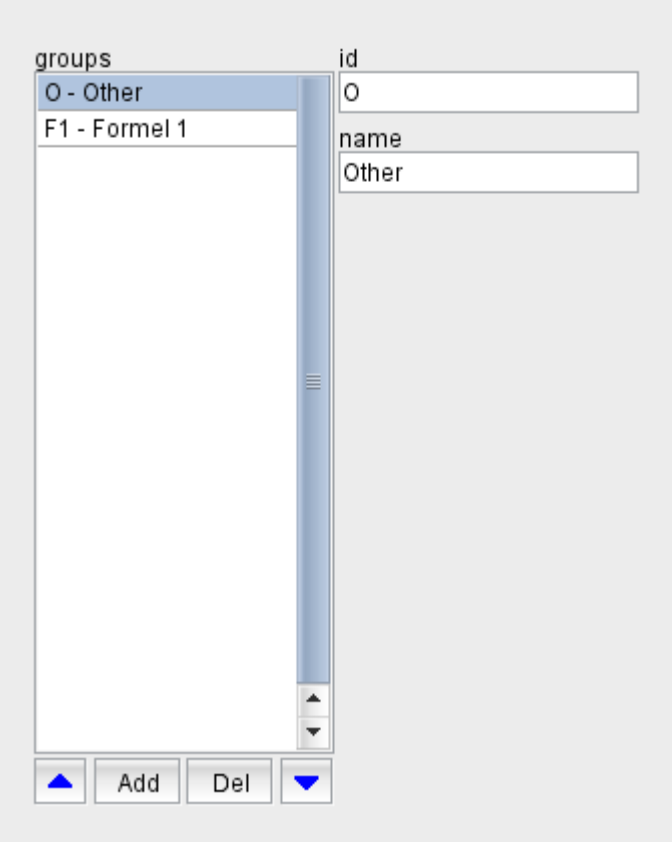
The configuration editor window is divided into 6 sections:Locations , Outgoing Lines , TX Devices , RX Devices , Groups and Profiles . While the last two sections work independently from the others, the sections Outgoing Lines , TX Devices and RX Devices always refer to the location actually selected in the Locations section.

The tool bar at the top of the window gives access to a number of global functions in the software. Below there is a short description for each of the toolbar buttons.

- --- The left field at the window's tool-bar shows the login-name of the user who is actually logged in. You may click with the mouse to this field, the program pops up the login/logout dialog. Please note, that you need a privilege level of 150 or higher to change the configuration of the software
- --- Writes the edited configuration back to the server. If you added or removed end points / devices this also changes the M&C device setup. In such a case a restart of the M&C server is necessary to make the changes effective. The software gives you the option to restart immediately or to postpone the restart.
- --- Reverts all changes.te .ts Opens the User Management Window .
- --- Shows the program version info.
- --- Shows this help page.

3.15.4.1 Groups

The sat-nms VioIP software lets you define groups of operators which only have access to a well defined part of the equipment. The VioIP Client Application is always started for one particular group and shows only the resources assigned to this group.



The group definition section is located in the top right corner of the application window. It shows the list of defined groups, selecting a group in the list shows the properties of this group right beside the list. You may edit the name of the selected group to your needs, the group name acts as a comment only. The group is uniquely identified by its ID, this cannot be changed once a group has been defined.

With the blue arrow buttons below the list, the selected group can be moved up and down in the list. The position of a group in the list is important inasmuch as the topmost group in the list is considered to be the default group.

The button "Add" lets you add a new group. The program shows a dialog window where you can enter the ID for the new group. An ID entirely consists of upper case letters and digits, the "-" character is allowed as separator. The ID must be unique, you cannot define two groups with the same ID. The ID also is unalterable, once you defined a new group you cannot change the ID of the group later.

The button "Del" lets you delete the selected group. The program shows a query dialog before the group actually gets deleted. The group you want to delete will probably be referenced by other resources, with these the following will happen:

- End point devices which belong to the deleted group will be moved to the default group. If you are going to delete the default (the topmost) group, the devices are moved to the group which will be the default group after the deletion. The very last group cannot be deleted. The software shows a second query dialog stating something like "9 devices will be moved from group 'A' to group 'B'" before the group deletion actually is done to inform

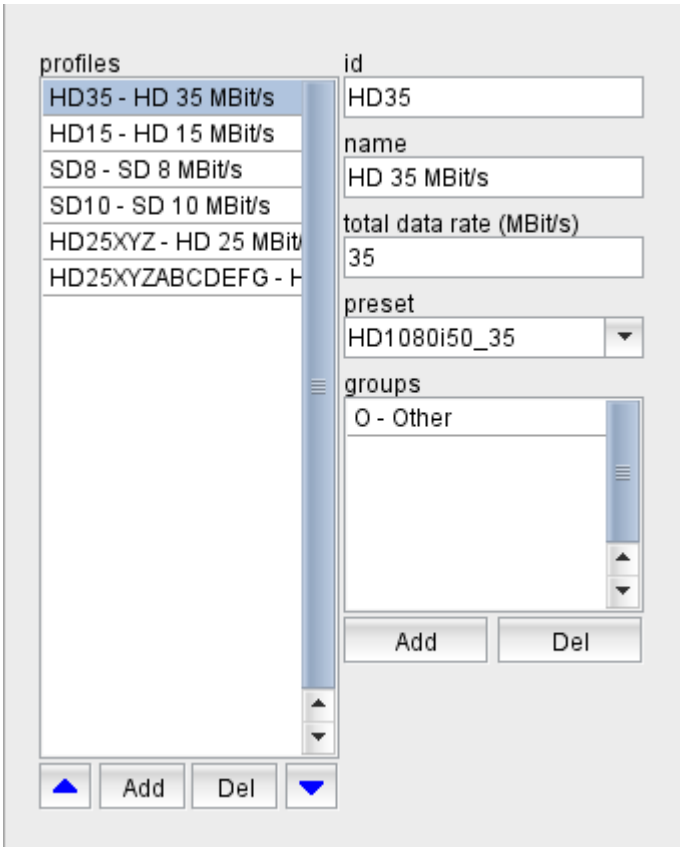
you what will happen if you delete this group.
- The group is removed from all profiles which had this group attached.

3.15.4.2 Profiles

Profiles define the data rate of the encoded stream, the video and audio encoding of the signal and many more parameters. The software uses a profile by applying a preset to the devices representing the end points of the upcoming connection.

To make a profile universally usable, presets with the name defined in the profile must be present for all types of encoder/decoder equipment used by the software. The software checks this when a new profile is defined.

There are device types which contain multiple encoders or decoders in one device frame. The software knows about these device types and expects a preset "NAME" to be present as "NAME-1", "NAME-2" ... "NAME-n" for all encoder or decoder instances this device may contain.



The profile definition section is located in the bottom right corner of the window. It shows the list of defined profiles, selecting a profile in the list shows the properties of this profile right beside the list. You may edit the properties of the selected profile to your needs. The profile is uniquely identified by its ID, this cannot be changed once a profile has been defined.

- *id:* The profile ID internally identifies the profile. It cannot be changed once the profile has been created.
- *name:* The profile name is shown in the VioIP Client Application in the list of active

connection and it is used to select a profile when the operator starts a connection with the "Activate selection (user defined)" button.

- *total data rate (MBit/s):* In this field enter the total data rate the encoded signal occupies on the data lines between the locations. The rate must match the data rate produced by the encoder preset and must include the rate of all contained streams including the transport stream format overhead. This is **not** the video data rate!.
- *preset:* With this field the name of the preset to be used for this profile is defined. The software presents a drop down list with all presets it finds for the device types known to be used as encoders / decoders within the VioIP software. The entry field also permits to overwrite the name and set a preset name which is not yet present. When the preset name is changed - either by entering a new name or by selecting a name from the list - the software checks if this preset is available for all known encoder / decoder device types. If not the software displays a warning. This means, you can define a profile which has the referenced presets not or not completely defined, but you are warned: You will not be able to start a connection with this profile if the referenced preset is not available for either the source or the destination device.
- *groups:* A VioIP Client Application will only permit to use this profile if the group ID the client has been started with appears in this list. This way you may define different profile settings for each particular group, each group will only see the profile definitions it has been granted permission. You may use the "Add" / "Del" buttons below the groups list to add or delete groups for this profile. If the group list of a profile is empty, it cannot be used.

With the blue arrow buttons below the profile list the selected profile can be moved up and down in the list. The topmost profile in the list is considered to be the default which is used for connections the operator starts without the "user defined" option.

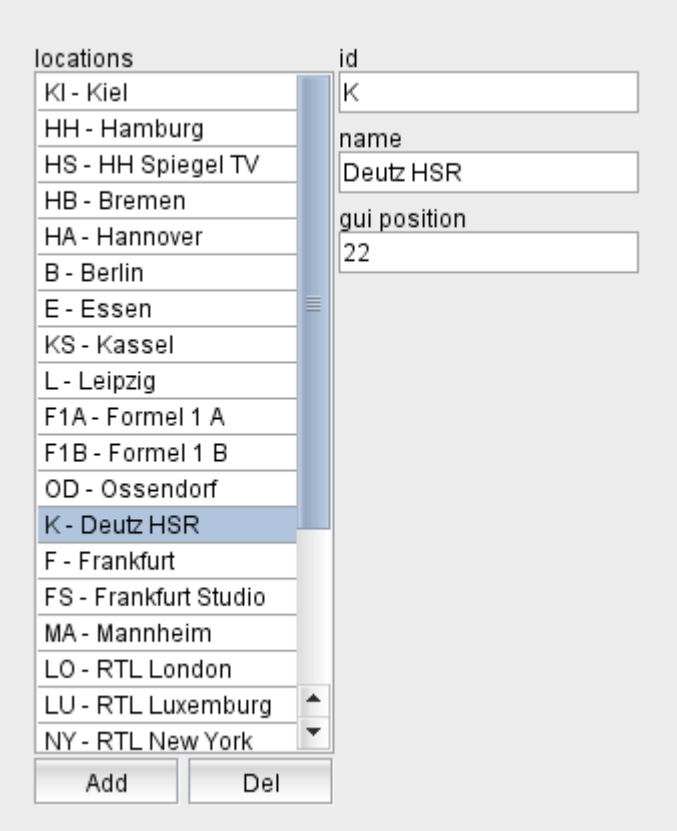
The button "Add" lets you add a new profile. The program shows a dialog window where you can enter the ID for the new profile. An ID entirely consists of upper case letters and digits, the "-" character is allowed as a separator. The ID must be unique, you cannot define two profiles with the same ID. The ID also is unalterable, once you defined a new profile you cannot change the ID of the profile later.

The button "Del" lets you delete the selected profile. The program shows a query dialog before the profile actually gets deleted. Deleting a profile does **not** delete the preset definitions referenced by this profile.

3.15.4.3 Locations

The section in the top left corner of the window shows the list of locations. Locations typically match rooms or cities, but strictly spoken 'locations' in the sense of this software are logically places which share a number of encoder/decoder devices which are connected in a network with virtually infinite bandwidth (i.e. the bandwidth of the network between the local devices is not managed by the software).

A location has a number of outgoing data lines and a number of TX and/or RX devices attached.



The 'locations' section shows the list of defined locations, selecting a location in the list shows the properties of this location right beside the list. Selecting a location also updates the data in the Outgoing Lines , TX Device and RX Devices sections to show these objects as they are available at the selected location.

You may edit the properties of the selected location to your needs. The location is uniquely identified by its ID, this cannot be changed once a location has been defined.

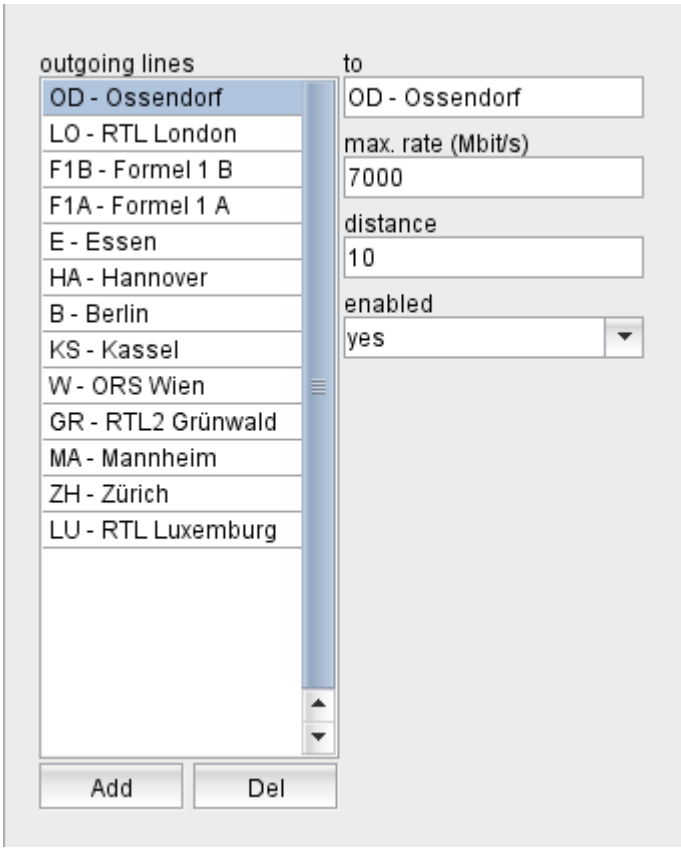
- *id:* The location ID internally identifies the location. It cannot be changed once the location has been created.
- *name:* The location name is shown in theVioIP Client Application as the label of the button representing the location in the TX/RX button arrays.
- *gui position:* The value in this field defines the position of the button representing this location in the button arrays. These arrays consist of 7 rows / 5 columns. A GUI position "1" addresses the button in the upper left corner, "5" in the upper right corner. "6" addresses the first button in the second row and so on. The special value "0" makes a location (temporarily) invisible. You cannot assign a GUI position twice, the program will decline this. If a new location is defined it automatically gets the first available GUI position assigned as a default.

The button "Add" lets you add a new location. The program shows a dialog window where you can enter the ID for the new location. An ID entirely consists of upper case letters and digits, the "-" character is allowed as a separator. The ID must be unique, you cannot define two locations with the same ID. The ID also is unalterable, once you defined a new location you cannot change the ID of the location later.

The button "Del" lets you delete the selected location. The program shows a query dialog before the location actually gets deleted. Deleting a location does **not** delete any sat-nms device definitions associated with this location.

3.15.4.4 Outgoing Lines

The section "outgoing lines" below the "locations" section defines the data lines which go from the selected location to other locations. The software manages data lines as unidirectional connections from location A to B. To define bidirectional lines, you have to define the line twice: once as a line from A to B and a second time as a line from B to A.



The section "outgoing lines" shows the list of data lines starting at the actually selected location. Selecting a line in the list shows the properties of this line right beside the list.You may edit the properties of the selected data line to your needs

- *to:* The ID and name of the destination location of this line. This field is read-only and cannot be changed.
- *max. rate (Mbit/s):* The maximum data rate which is available for the VioIP application on this line. The software uses this to examine if there is enough bandwidth available for a new connection.
- *distance:* The virtual distance between the two locations connected by this line. The software uses this number to calculate the data route between two locations using the Dijkstra algorithm. For details see the paragraph at the end of this page.
- *enabled:* This switch lets you temporarily disable a line without removing the line from

the configuration.

The button "Add" lets you add a new line. The program shows a dialog window where you can select the destination location for the line.

The button "Del" lets you delete the selected line. The program shows a query dialog before the line actually gets deleted.

Route Calculation

In the VioIP system the route from one location to another is determined by the settings of the IP routers in the system and by source/destination IP addresses. To calculate the available bandwidth between two locations, the software must know the way the IP packets take, specially when the route goes over several hops. The available bandwidth then is calulated as the minimum bandwidth available on any line on this route.

The software uses for this the "shortest path" algorithm by Dijkstra: Each line has assigned a "distance" value, the total distance of a route is the sum of distances of all hops of the route. From all possible routes the software chooses the one with the shortest total distance.

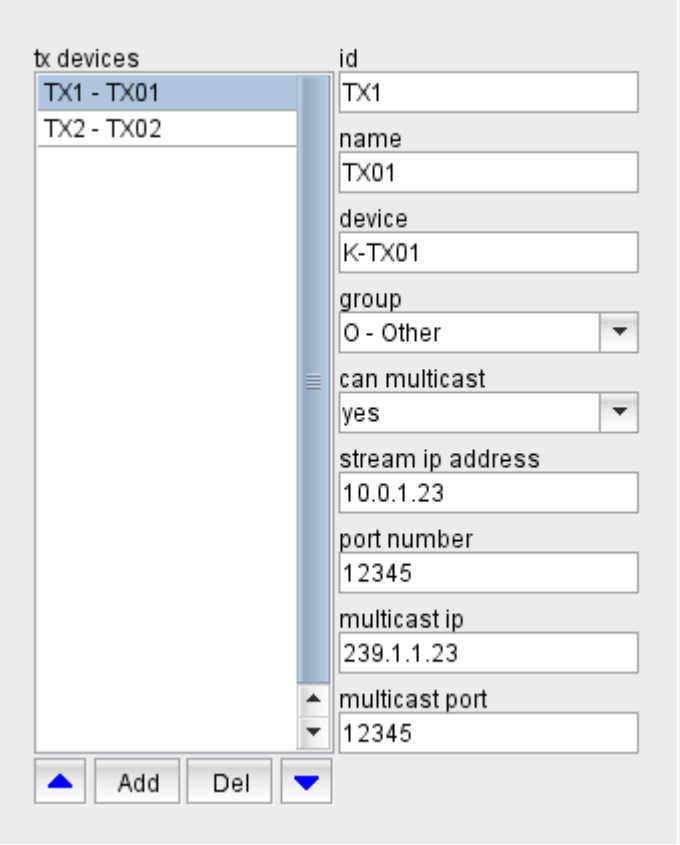
As the software cannot read the settings of the routers used in the network, it is important to set the "distance" parameters in a way that the routes calculated by the VioIP software match the routing programmed in the IP routers. You may check the routes actually used in the software in the VioIP Client Application : Select a source location in the TX button array and then right-click the destination in the RX button array and select "Show route to here". The program displays a pop up window with the route.

3.15.4.5 TX Devices

The section "tx devices" manages the transmit devices or more strictly spoken the transmit side connection end points available for the selected location. This usually comprises more than the plain encoder device.

A transmit side connection end point consists of the following components:

1. The data stored about this end point in the VioIP configuration database.
2. A logical end point (VioIP-End-Point) device representing the connection end point in the sat-nms M&C software. The logical end point device receives abstract commands to start or stop a connection and translates this abstract command into the particular settings expected by the physical end point device. There is always exactly one logical end point device for a connection end point.
3. A physical end point device in the sat-nms M&C software. This device - typically an encoder - gets the video signal at its input and creates an IP stream sent over the network. There are devices containing more than one encoder unit in one physical device frame. Hence it is possible that multiple logical endpoint devices share the same physical device. A so called "module index" is used to identify the encoder unit which shall be used.
4. Optionally there may be a file recorder device assigned to the connection end point. This file recorder logs quality parameters of the physical endpoint device like packet counters.



The section "tx devices" shows the list of tx devices available at the selected location. Selecting a device in the list shows the properties of this device right beside the list. You may edit the properties of the selected device to your needs

- *id:* The device ID internally identifies the device. It cannot be changed once the device has been created.
- *name:* The name of the device.
- *device:* The name of the VioIP-End-Point device representing this end point in the sat-nms M&C software.
- *group:* The group this device is assigned to. The device is only visible / accessible for a VioIP Client Application started for the ID of this group .
- *can multicast:* Set this to "yes" if the physical device representing this end point is capable to create a multicast stream.
- *stream ip address:* Enter the IP address of the stream port of the device here. This is the source address of unicast streams sent by this device. The address usually is not actively commanded at the device, however the value entered here must match the address configured in the device.
- *port number:* This is the port number of the source of a unicast stream. Usually this value doesn't matter as the device uses a random port number for this.
- *multicast ip:* The multicast address / group to be used in multicast mode.
- *multicast port:* The port number to be used in multicast mode.

With the blue arrow buttons below the device list the selected device can be moved up and down in the list. When the software searches for the first available deviceThe topmost device

which is used for connections the operator starts without specifying a device explicitly, it goes through this list from top to bottom.

The button "Add" lets you add a new device. The program shows a dialog window where you can enter the ID for the new device. An ID entirely consists of upper case letters and digits, the "-" character is allowed as a separator. The ID must be unique, you cannot define two devices with the same ID. The ID also is unalterable, once you defined a new device you cannot change the ID of the device later.

When you entered the ID for new device, the software shows in a next step a dialog which lets you select which aspects of the connection end point actually shall be created and how these aspects shall be initialized. Chapter Adding New Devices later in this document describes this dialog more elaborately.

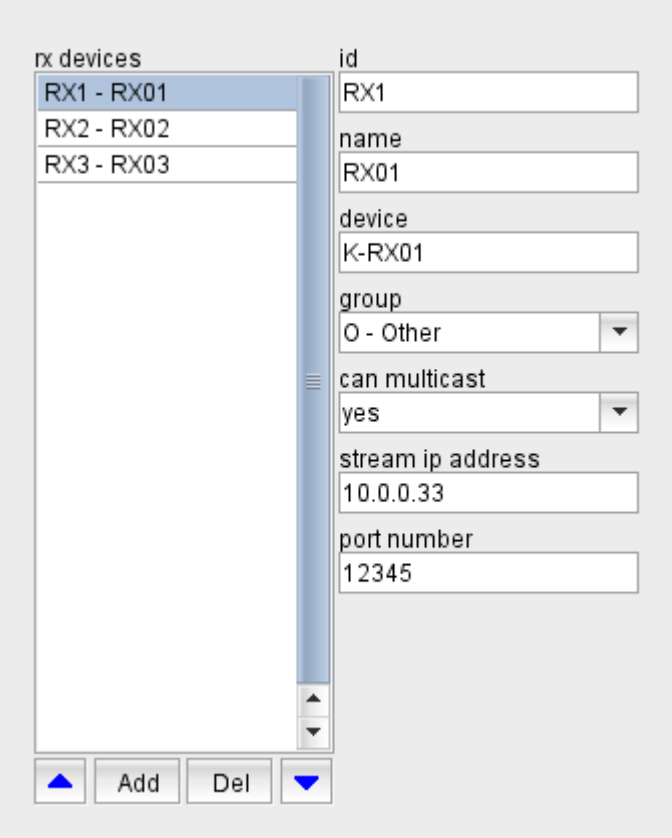
The button "Del" lets you delete the selected device. The program shows a query dialog before the device actually gets deleted. The dialog lets you select if the software shall remove the VioIP-End-Point device, the physical device and an optional file recorder device as well from the M&C system configuration.

3.15.4.6 RX Devices

The section "rx devices" manages the receive devices or more strictly spoken the receive side connection end points available for the selected location. This usually comprises more than the plain decoder device.

A receive side connection end point consists of the following components:

1. The data stored about this end point in the VioIP configuration database.
2. A logical end point (VioIP-End-Point) device representing the connection end point in the sat-nms M&C software. The logical end point device receives abstract commands to start or stop a connection and translates this abstract command into the particular settings expected by the physical end point device. There is always exactly one logical end point device for a connection end point.
3. A physical end point device in the sat-nms M&C software. This device - typically a decoder - receives the IP stream at its input and decodes it to the contained video / audio signals. There are devices containing more than one decoder unit in one physical device frame. Hence it is possible that multiple logical enpoint devices share the same physical device. A so called "module index" is used to identify the decoder unit which shall be used.
4. Optionally there may be a file recorder device assigned to the connection end point. This file recorder logs quality parameters of the physical endpoint device like packet counters.



The section "rx devices" shows the list of rx devices available at the selected location. Selecting a device in the list shows the properties of this device right beside the list. You may edit the properties of the selected device to your needs

- *id:* The device ID internally identifies the device. It cannot be changed once the device has been created.
- *name:* The name of the device.
- *device:* The name of the VioIP-End-Point device representing this device or end point in the sat-nms M&C software.
- *group:* The group this device is assigned to. The device is only visible / accessible for a VioIP Client Application started for the ID of this group .
- *can multicast:* Set this to "yes" if the physical device representing this end point is capable to receive a multicast stream.
- *stream ip address:* Enter the IP address of the stream port of the device here. This is used as the destination address of unicast streams sent to this device. The address usually is not actively commanded at the device, however the value entered here must match the address configured in the device.
- *port number:* This is the destination port number for the unicast stream.

With the blue arrow buttons below the device list the selected device can be moved up and down in the list. When the software searches for the first available deviceThe topmost device which is used for connections the operator starts without specifying a device explicitly, it goes through this list from top to bottom.

The button "Add" lets you add a new device. The program shows a dialog window where you can enter the ID for the new device. An ID entirely consists of upper case letters and digits, the "-" character is allowed as a separator. The ID must be unique, you cannot define two devices with the same ID. The ID also is unalterable, once you defined a new device you cannot change the ID of the device later.

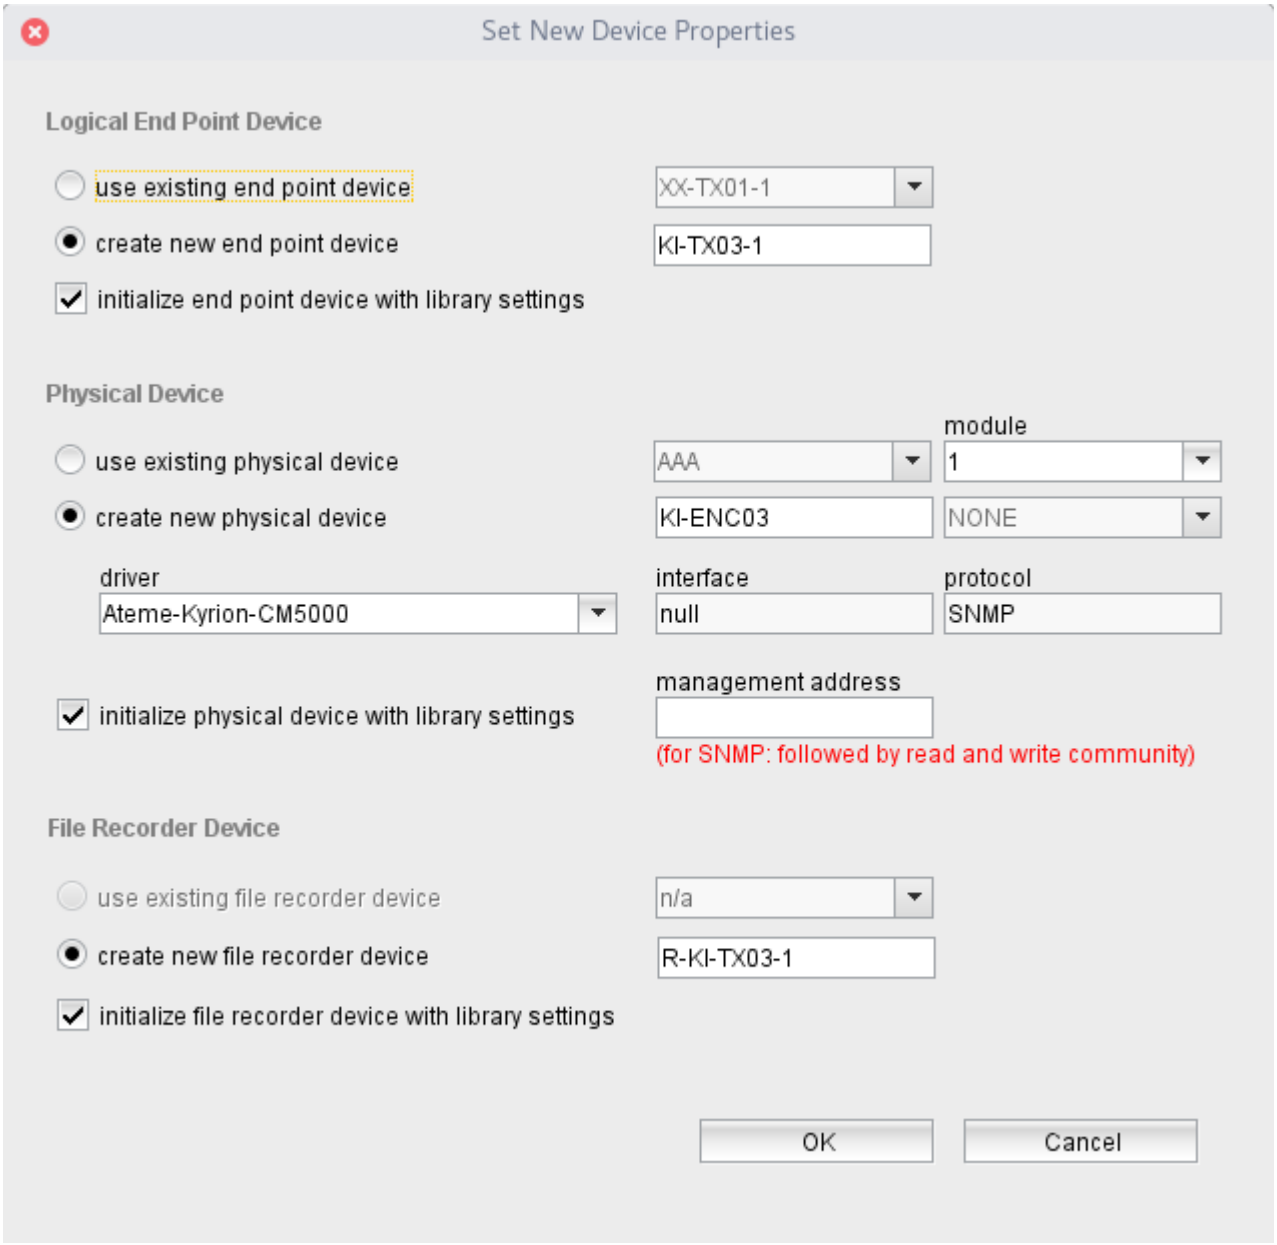
When you entered the ID for new device, the software shows in a next step a dialog which lets you select which aspects of the connection end point actually shall be created ans how these aspects shall be initialized. Chapter Adding New Devices later in this document describes this dialog more elaborately.

The button "Del" lets you delete the selected device. The program shows a query dialog before the device actually gets deleted. The dialog lets you select if the software shall remove the VioIP-End-Point device, the physical device and an optional file recorder device as well from the M&C system configuration.

3.15.4.7 Adding New Devices

The button "Add" below the list of TX or RX devices lets you add a new device. The program shows a dialog window where you can enter the ID for the new device. An ID entirely consists of upper case letters and digits, the "-" character is allowed as a separator. The ID must be unique, you cannot define two devices with the same ID. The ID also is unalterable, once you defined a new device you cannot change the ID of the device later.

When you entered the ID for new device, the software shows in a next step this dialog which lets you select which aspects of the connection end point actually shall be created and how these aspects shall be initialized.



The first section in this dialog refers to the logical end point device which represents the new connection end point to create. You have the choice either to use an existing VioIP-End-Point device in the M&C for this or to create a new one.

You can select the first choice only if there areVioIP-End-Point devices in the M&C which are not yet used for the VioIP software. The software offers a list of such devices in this case, you can select one from this drop down list.

If you select to create a new logical end point device, the software suggests a name for this device, made up from the location ID and the device ID you specified in the previous step.

Finally the checkmark "initialize end point with library settings" defines if the setup of the used or newly created device shall be initialized with settings derived from choices made in the next step concerning the physical device. This includes the faults to be monitored at the physical

device and the start/stop macros used by the logical end point device to perform the start and stop of a connection.

The next section is all about the physical device to be used for the end point. Again you have the choice either to use an existing device or to create a new one. Using an existing device is speically useful to use an unused module in a multi-encoder or multi-decoder device. Regardless of your choice you have to specify a module index beside the device name if the device containes multiple modules.

If you decide to create a new physical device you should select the device driver for the new device as the next step. Selecting the driver sets the communication interface and communication protocol defaults and suggests a name suitable for the new device.

The next step is to specify the management address for the new device. For devices controlled via SNMP the address should contain also the read and write community names (e.g. "10.0.0.1 public private").

The checkmark "initialize physical device with library settings" defines if the setup of the used or newly created device shall be initialized with settings derived from choices made in the next step concerning the physical device. This is important for multi-encoder or multi-decoder devices because this masks stream specific faults of the device in a way, that these faults do not interfere with the state of other streams on the same device.

The last section of the dialog defines the optional file recorder which may be used to log the values of packet counters of the physical device. Like the logical end point device, the file recorder is a logical device and the options given for this device are very similar to the options for the logical end point.

You may choose between using an existing device (if one is available) or to create a new one. Checking "initialize file recorder with library settings" lets you automatically initialize the file recorder to monitor the packet counter parameters of the physical device selected above.

3.16 M&C Configuration

This section of the manual describes how to configure the sat-nms M&C software for the device configuration of the ground station to control and how to create an application specific user interface consisting of one or more screens.

The following chapters refer to the legacy Java client user interface of the software, they only are applicable to software installation which still or explicitly use the Java client as user interface.

New M&C installation should preferably use the Web based user interface which provides equivalent funtions to configure the software for a specific task.

3.16.1 Configuring The Device Setup

With the sat-nms M&C or VLC software, the assignment which type of device is controlled by which serial interface is free configurable. The user interface of the software provides a

configuration window which enables the authorized operator to setup the software.

Chapter ' The Device Setup Editor Window ' describes the usage of this configuration tool and guides through setup of a M&C system or VLC. The now following chapter introduces the underlying concepts of the M&C / VLC device configuration.

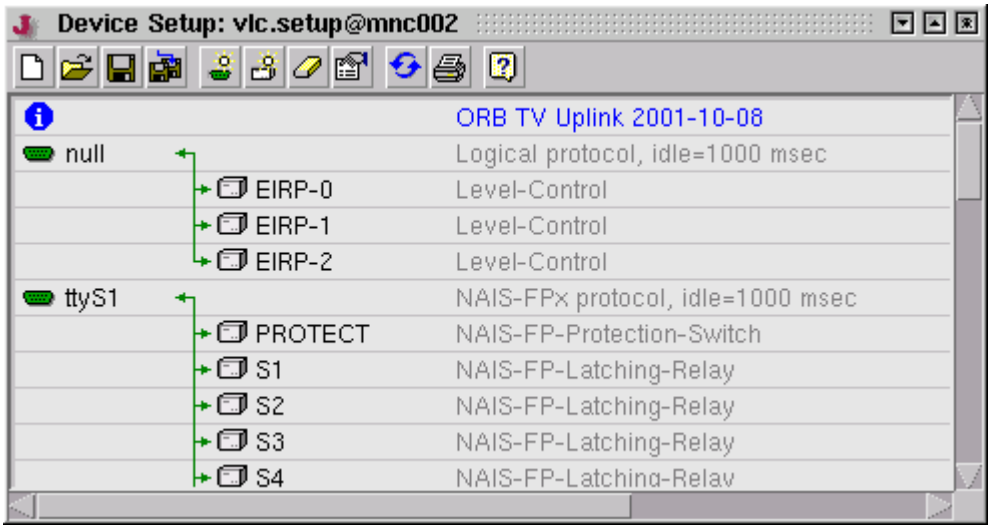
3.16.1.1 Concepts

When an operator is going to configure a VLC or M&C first it is important to understand, that with the sat-nms software each serial interface is bound to a communication protocol. The communication protocol used for a certain device is not unchangeably linked to the device driver. This is to support multiple devices being controlled via a single interface. Devices using a common 'multi drop' capable protocol may be connected to the VLC / M&C with a RS485 bus. This way one can for example operate a ND-SatCom upconverter and a CPI TWTA with a single RS485 interface. Both device types use the same communication protocol, they may share the same RS485 bus.

Once an interface (serial port) has been included into the setup and got a communication protocol assigned to it, within the setup devices can be attached to this interface. With the device definition, the device gets a name and a device driver assigned to it. The device's name acts as an address within the software where to send at commands (equipment settings) to, the device driver tells the software how to treat the device at a low communication level.

3.16.1.2 The Device Setup Editor Window

The 'Device Setup Editor' lets you define / modify the equipments setup, i.e. the assignment of monitored/controlled devices to the physical interfaces of a VLC or M&C computer. You need to be connected on-line and logged in as a fully authorized operator to edit the equipment setup.



As shown in the figure above, the editor presents the equipment setup as a list of interface and device definitions. Green arrows connect the devices with the interface they use to communicate with the computer.

In the VLC/M&C computer, the equipment setup is stored as a file 'vlc.setup'. This file is read by the M&C server software on startup. Changes you make in the editor window are temporary until save this file to the target system (the function). A changed equipment setup you stored on the target machine will become effective when the M&C server application gets restarted.

Tool-bar Functions

- --- Clears the setup, lets you define a new setup from scratch.
- --- Loads a equipment setup from disc. With a NMS system the file is loaded from the NMS server, not from the VLC.
- --- Saves the edited setup as 'vlc.setup' to the target computer. It will use this equipment setup with the next start.
- --- Saves the edited setup with a different file name. Setup definitions are stored in a folder 'setups' which is located at the NMS server computer with NMS systems, on the M&C server computer with M&C systems.
- --- Adds a new interface definition. The definition is inserted just below the actually highlighted one.
- --- Adds a new device definition to the setup. The new definition is inserted just below the actually highlighted one unless the latter describes an interface. In this case, the new definition gets appended at the end of the list of devices already connected to this interface
- --- Deletes the actually highlighted definition.
- --- Lets you edit/change the actually highlighted definition. You also may double click to the definition for this.
- --- Restarts the M&C server application on the target computer. You must do this, to make the target system use a modified equipment setup. With a M&C application, this will break the user interface's connection to the server. With a NMS/VLC application the VLC will go off-line with the restart. You should wait at least 2 minutes before you try to connect again.
- --- Prints the edited setup.

Multiple Devices At One Interface

With RS232 interfaces, you will connect one piece of equipment to one interface in most cases. However, there are a couple of situations where multiple devices at one interface make sense:

- The *null* interface is used by all logical devices. In every VLC/M&C system there is exactly one *null* interface running the *Logical* protocol. All logical devices are connected to this (physically not existent) interface.
- When using an RS422/485 interface, you may connect several devices to a bus and control them through one interface. The precondition for this is, that **all** devices at this interface use the **same** communication protocol supporting this kind of multi drop operation.
- Devices for switches, alarm circuits etc. which rely on the Matsushita FP0 PLD, are assigned to the same interface as long as they are implemented by the same FP0 device.

Storing Setups For Backup Or As Templates

With an NMS application you are encouraged to backup every equipment setup at the NMS site by means of the 'save as ( )' function. This backs up the settings at a central place and builds a set of template setups.

Restarting The Target System

When modifying an equipment setup, be sure to store the changes setup using the - function and then to restart the target with . Without restart, the target continues using the old setup until a restart occurs for some other reason.

Stored Equipment Settings

Apart from the plain interface assignments done by this configuration window, the equipment setup comprises a large number of settings like interface line speeds, device addresses etc. When changing device names, be aware that these settings are lost.

3.16.2 Arranging The User Interface

The sat-nms software contains a powerful tool which enables the operator to customize or even create user interface screens which are nice looking and easy to operate. The tool, called the ' Screen Editor ', works much like a vector based drawing program. It lets the user place various kinds of objects (editing fields for settings, textual or graphical status displays and much more) into the screen to edit.

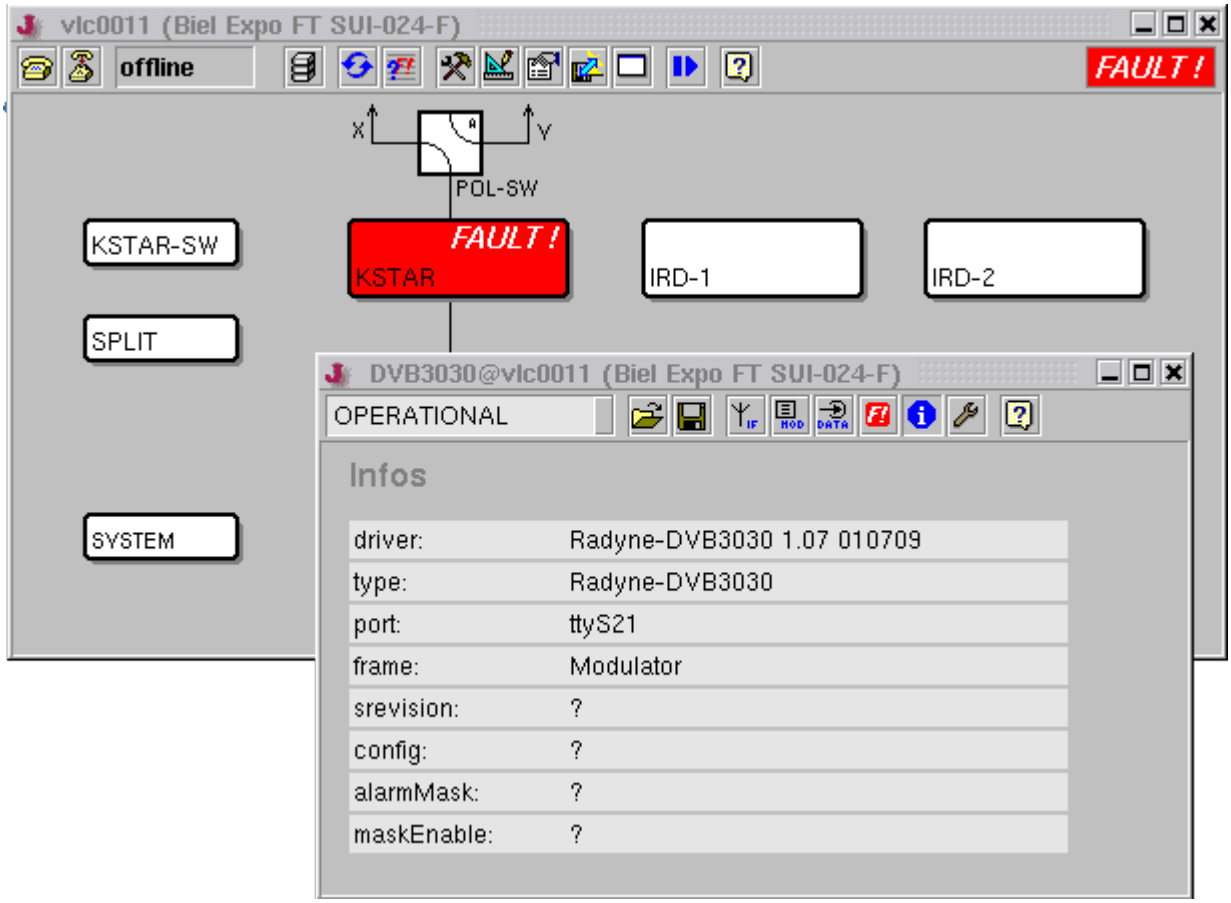
The software comes with predefined screens for each device type. These screens can be used to create a hierarchical structured user interface with a few mouse clicks. On the other hand, the configuration capabilities of the sat-nms user interface are powerful enough to create special user interface screens exactly matching the operator's needs.

3.16.2.1 Concepts

The software foresees one main screen for each M&C / VLC. With a M&C this main screen automatically is shown when the user interface program is started. With a VLC, the 'VLC Main Window' contains this screen. The user interface may be configured to use more than one screen which are switched on the operator's request, either shown in the same window or in separate windows.

Device oriented user interface

There are two major approaches to design and configure a user interface for the sat-nms software. The first one, called the 'device oriented user interface', results in a hierarchically structured user interface. It makes use of the predefined windows / screens coming with the software and can be created with only a few mouse clicks.



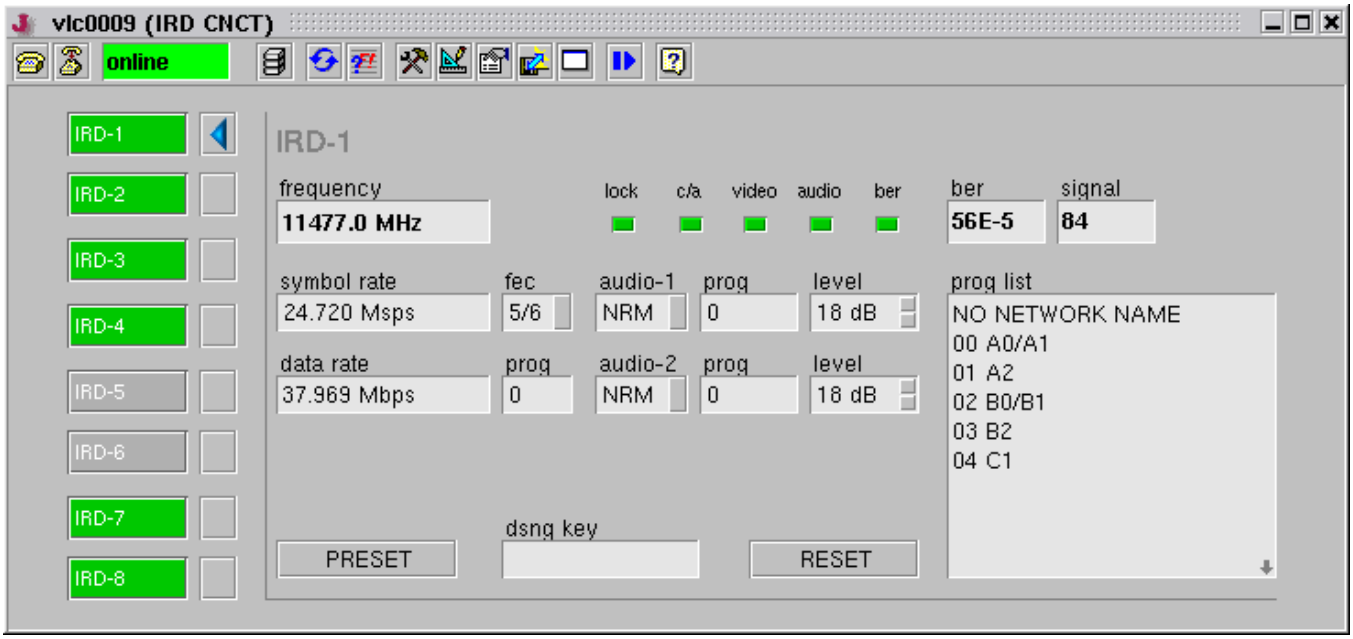
Example for a device oriented user interface.

With the device oriented user interface, the main window contains a so called device icon for each device which is controlled by the M&C/VLC. This icon is labeled with the device's name and shows the OK/FAULT state of the device with it's color. A double click to a device icon opens the ' Device Window ' for this device, containing the predefined screens for this device type. Using the ' Device Window ', all parameters of a device supported by the sat-nms software can be monitored or controlled.

To create a main screen for the device oriented user interface, thescreen editor provides a function adding a device icon for each device in the system on a single mouse click.

Task oriented user interface

While the device oriented user interface follows predetermined structures, the so called 'task oriented user interface' is entirely customer designed. Using the screen editor , the user places entry fields or status displays in the screen for each parameter he wants to include to the user interface.



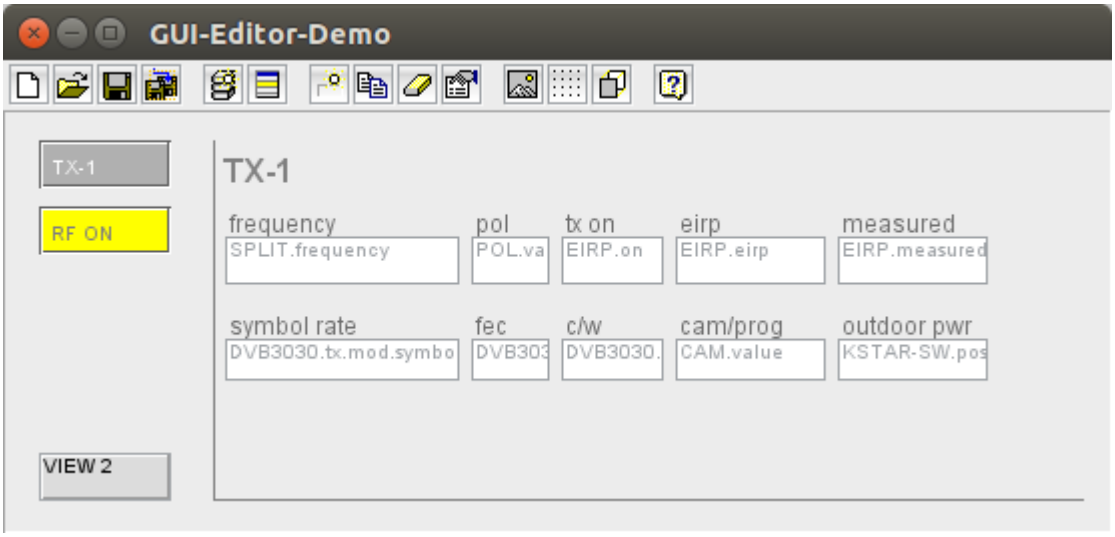
Example for a task oriented user interface.

A task oriented user interface not necessarily contains all available parameters. To keep the user interface clear, only those parameters are included, which the operator needs to fulfill the task the user interface is designed for. Moreover, there also is no need to group parameters by the device they belong to, like the device oriented user interface does. Parameters belonging to diverse devices freely may be mixed in one screen.

3.16.2.2 The Screen Editor Window

The Screen Editor window is used to layout the M&C windows used in the M&C/NMS user interface. Windows like the VLC Main window, the M&C Main window and additional user created windows are customized by means of this program.

The Screen Editor works like a simple drawing program. Each M&C window contains a number of objects (elements) which may be placed, sized and edited using the Screen Editor.



Object Placement

Objects contained in the window are placed by dragging them to the desired position (left mouse button). Dragging an object with the right mouse button changes it's size, or, more precisely changes the size of it's bounding rectangle (most objects are not scaled if they are resized). A double click to an object opens the Element Properties window for this object.

Tool-bar Functions

- --- Clears the window surface and starts to edit a new window.
- --- Loads a window description to edit.
- --- Saves the window actually edited.
- --- Saves the window actually edited with a different name. If you have selected a group of elements, only the selected elements are saved. This deletes all unselected elements and shrinks the panel just to fit around the selected elements! The saved screen always ist stored in the "/screens" directory. This applies even if you edited a VLC screen from within the NMS client application.
- --- Adds a new device icon for each device which has not yet an icon. This function is only available, if the program knows about the device list of the application which is edited.
- --- Adds a new object to the window. It appears in the upper left corner. You also may point with the mouse to the (empty) destination point at the drawing area and the right button context menu.
- --- Duplicates the selected object. The new object appears on top of existing one.
- --- Removes the selected object. If you have selected a group of elements, all elements in the group are removed.
- --- Opens a Element Properties window for the selected object.
- --- Defines a background image for the window. A file selection box appears, you may select any picture in GIF or JPG format as the window background. The window size automatically gets aligned to the size of the image you selected.
- --- Objects are placed along a invisible 3 x 3 pixel grid if they are moved while this

button is down.
- --- Moves the selected object to the back so it does not cover any other object.

Inserting screens

You may insert complete screens into the actually edited one. Point the mouse to where you want the upper left corner of the inserted screen to be placed. Press the right mouse button and select "Insert screen" from the context menu. A file selection box appears which lets you select the screen to insert.

You also may select one of the predefined screens used by the device windows of the software for insertion. To insert such a file, change the directory to "dscreens" in the file selection box. Be aware, that the message identifiers of all parameters in these screens don't contain a device ID. The tx-on parameter of a transceiver e.g. refers to a message ID "tx.on" in a device screen, not to something like "KSTAR-1.tx.on". You have to edit all message identifiers if you insert a screen from this directory.

Group selections

The screen editor lets you select multiple elements to a set on which you can perform some useful actions. Selecting an element group works like you would expect: Spanning a rectangle by dragging the mouse with the left button held down selects all elements which are covered by this rectangle. Selecting single elements with the mouse while pressing down the CTRL key at the keyboard also adds these element to the group. Any other mouse click clears the selection.

Elements selected in this way are marked with a blue rectangle drawn around. The first element you selected is called the "reference element". It's marked with four small boxes in it's corners. If you select a group by spanning a rectangle around the elements, the element which was selected before becomes the "reference element". Below there is a list of operations you may apply to a selected group of elements:

- Moving a group of elements: --- Select the elements you want to move, then keep the CTRL key pressed and drag one of the elements in the group (left mouse button). The other elements follow.
- Resizing a group of elements: --- You can change a group of elements to the same width, height or size the reference element has. Select the elements you want to resize and select the reference element. Then -- while pressing the CTRL key -- open the context menu with the right mouse button on one of the elements in the group. Select "Same width", "Same height" or "Same size" as you need.
- Aligning a group of elements: --- Aligning a group of elements, i.e. moving them to make either the left, right, top or bottom edge of all elements in one line, is done analogous to the resizing functions. The context menu selections are "Align left" ... "Align bottom". "Align column" is a special function which aligns the selected elements horizontally to the reference element like "Align left". Vertically this function aligns the elements to fit into a fixed 42 pixel raster, relative to the reference element.
- Re-addressing a group of elements. --- With this function (context menu selection "Same device") you can address a group of elements to the same device name the reference element contains in it's message ID. The device name in the message ID of each element

in the group gets replaced by the device name in the reference element's message ID. This function recognizes if an element contains no device name defined and adds the reference element's device name in this case.

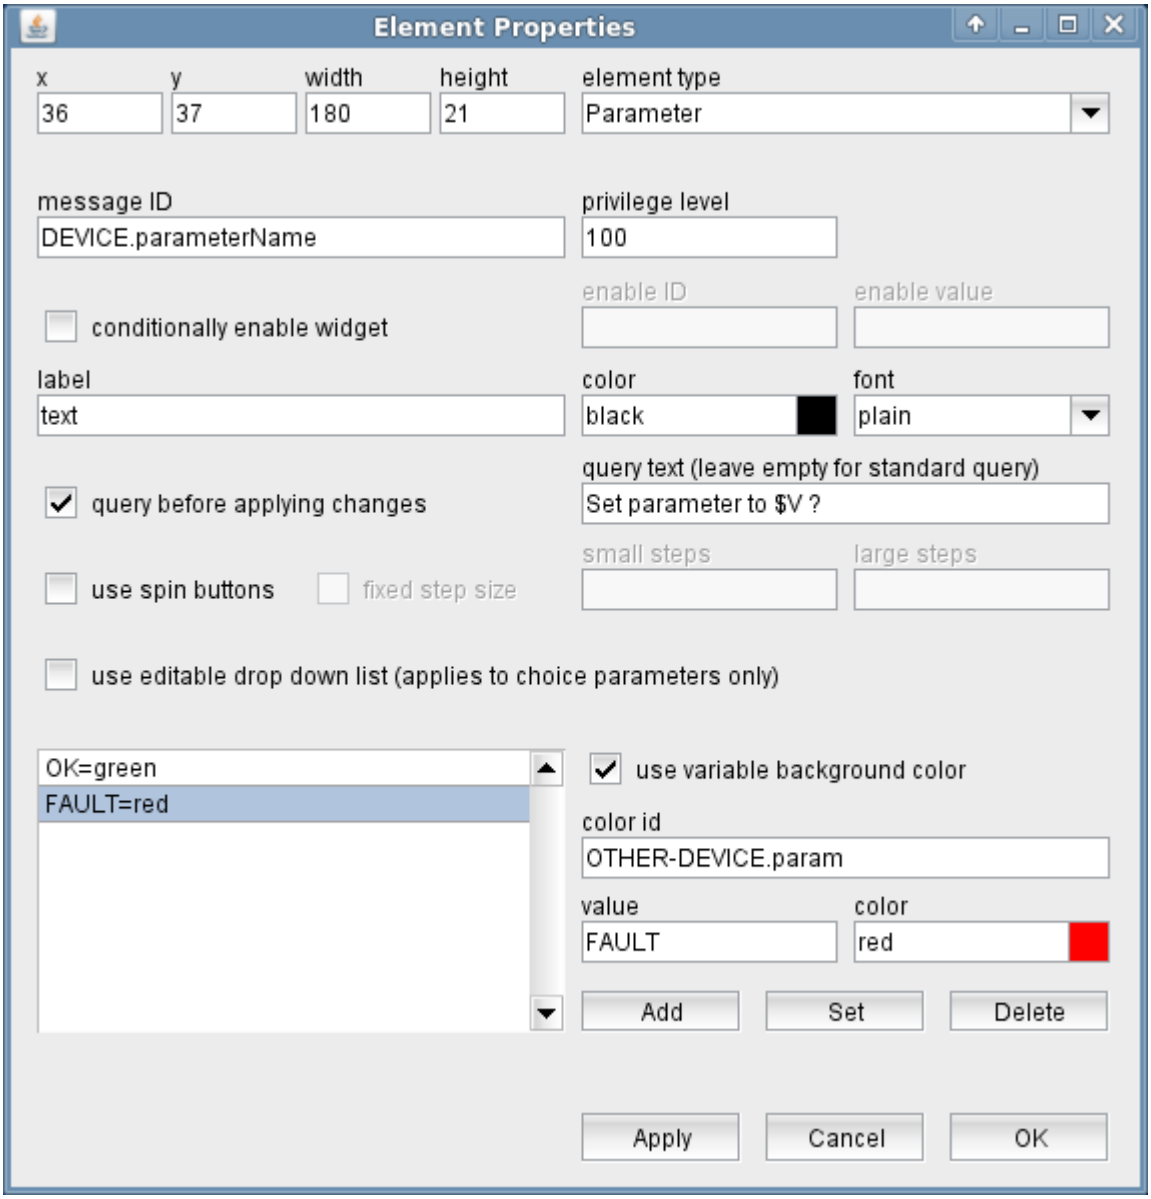
- Storing a group of elements: --- Select the elements you want to store and click to in the tool bar. This deletes all unselected elements and shrinks the panel just to fit around the selected elements, so be careful! In most cases it will be better to make a backup of the edited screen before.
- Deleting a group of elements: --- Select the elements you want to delete and click to in the tool bar.

Remarks

- Window descriptions, images and icons are stored on the NMS server computer. This means, any changes you make are stored at a central place and are automatically available to other users. If you wand to add your own icons or images, contact your system administrator to store these files on the server computer.
- A quick start for a new main screen is the tool bar button. It creates a new device icon for each device defined in the VLC/M&C system.

3.16.2.3 The Element Properties Window

The Screen Object Properties window is used to set the properties of a display object within the Screen Editor . Depending on the type of screen element, the window may contain different fields / information, below the element properties window for the common parameter element is shown as an example:



Although the contents of the element properties window depends on the type of element shown, the first line of the window is always the same:

- x --- X location of the element in the window.
- y --- Y location of the element in the window.
- width --- Width of the element's bounding box.
- height --- Height of the element's bounding box.
- element type --- The object type of the element.

Remarks

- If you change an element's position by dragging it with the mouse, this will overwrite any position / size values values edited in the element properties window. Clicking "Apply" before the element is moved saves the edited values.
- Changing the element type also changes the shape of the element properties window. As

the element properties internally are stored in a way compatible to older software versions, the content of some fields may change in a way you might not expect.
- The screen editor uses the same Element Properties window for all elements. If you click to another element in the editor window, the properties of this element get loaded into the properties window.

3.16.2.4 Display Element Types

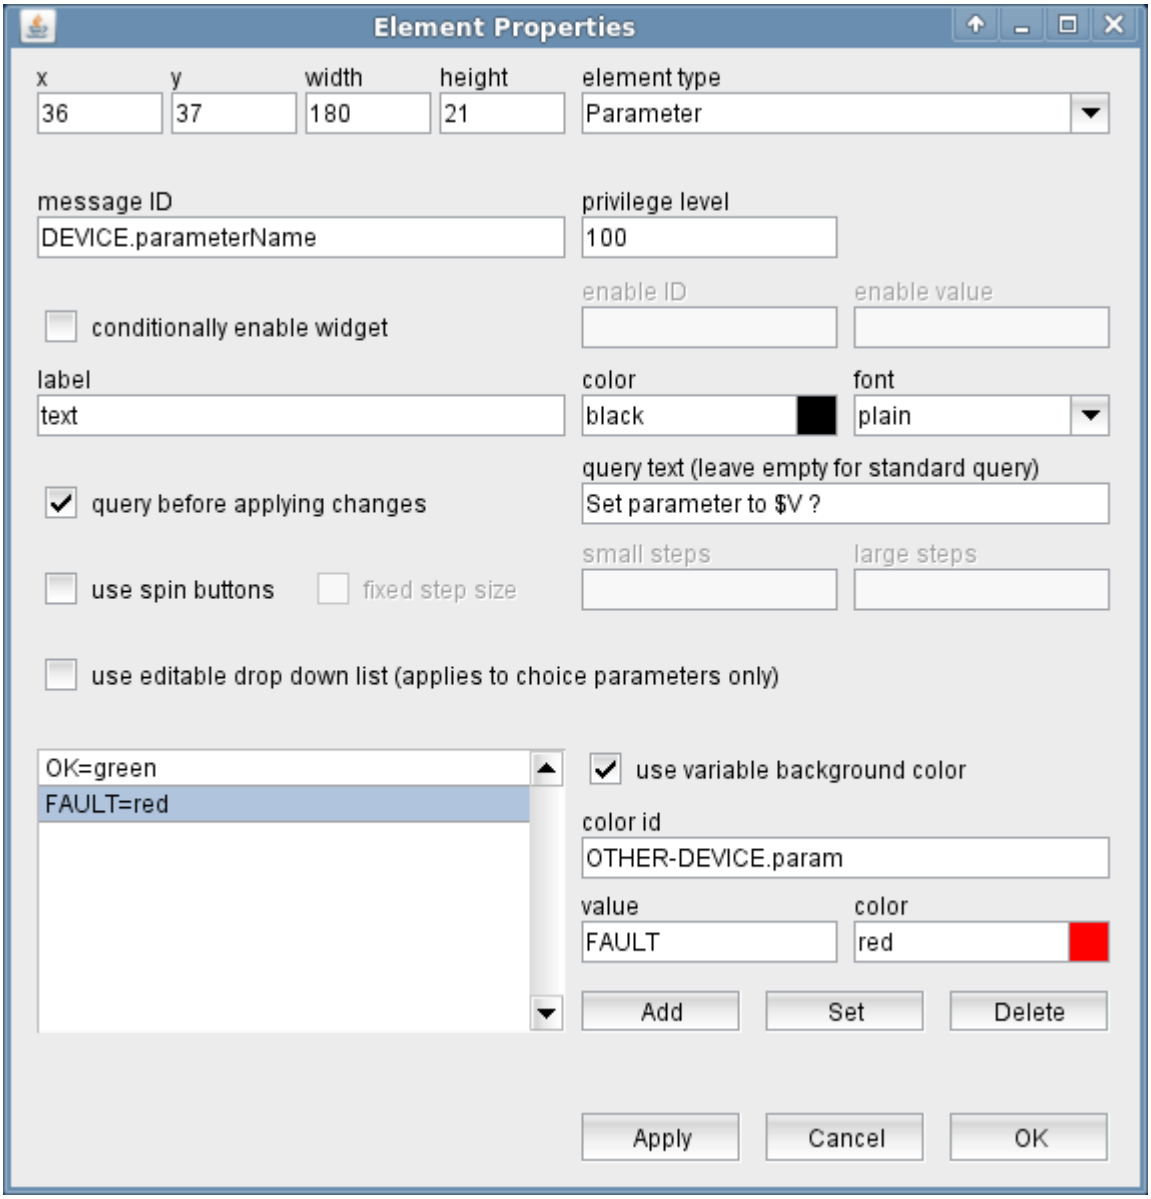
The table below shows the types of display elements the screen editor supports. A detailed description of the individual element types is given on the following pages.

Element Type	***Description***
Parameter	A parameter entry field.
Read-Only Parameter	A parameter display field which does not allow the parameter to be edited.
Radio Buttons	A parameter entry field specially for CHOICE parameters.
Fault	A special display element to display a fault flag. It shows the textual description of the fault and it's state in an entry field frame. The right mouse button shows a context menu to change the fault's priority.
Label	Displays a single line of text.
3D Frame	Draws a sunken 3D frame, may be used to group parameters.
Rectangle	Draws a rectangle.
Line / Arrow	Draws a horizontal/vertical line or arrow.
Icon	Places an icon (GIF or JPG image) into the screen. Optionally the icon can be programmed to change with a parameter value.
EDIT Button	Places an EDIT button into the screen, implicitly forcing the EDIT/TAKE operating method for this screen instead of changing each parameter independently.
TAKE Button	Places a TAKE button into the screen.
LOCK Button	A button to control the lock state for exclusive operation for a number of devices.
Device Icon	Places an icon into the screen which represents a device. This icon will display the device's operating/fault state by it's color / shape.

Element Type	***Description***
Switch Icon	Like the device icon. but additionally displays the actual position of a switch (Meant to be used for block diagrams showing the true signal path.
Frame Button	Defines a button which launches another screen, e.g. for detail views.
Parameter Button	A button which sends a certain parameter value when pressed.
Latching Button	A button which displays/controls a 2-state parameter using it's pressed state.
Gauge	A gauge element, displaying a numeric parameter as a horizontal bar.
Strip Chart	A strip chart element, displaying a numeric parameter as an y/t diagram that automatically advances with 1 pixel / second.
Spectrum Display	The spectrum display element integrates the spectrum display of a spectrum analyzer device in a user screen.
MCP Display	The MCP display element integrates the measurement display of a spectrum analyzer device in multi channel measurement mode in a user screen.
ODM Target List	The ODM Target List element shows the list of targets of aSatService-ACU-ODM antenna controller device. It permits to recall, save or delete target definitions of this type of antenna controller. It is specialized to this antenna controller, does not support other types.
XY Chart	This element shows the relation of two numeric variables in an X/Y diagram, featuring a trace which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.
JSON List	This is a special screen element required for some devices which distribute a state table/list in JSON format.
Thumbnail Icon	A screen element to show thumbnail images from the video processed by an encoder / decoder / gateway device which supports this feature.

3.16.2.4.1 Parameter

The *Parameter* display element is the common component to display and edit most types of M&C parameters. Depending on the data type of the parameter (the data type is detected automatically) the parameter elements appears as textual / numeric entry field, choice box or as display field for read only parameters. In the screen editor, the parameter element is shown as a sunken rectangle.



The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses the parameter the element shall display or edit. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the ' Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- privilege level --- The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.

- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the entry field.
- label --- The label text is drawn above the element.
- color --- The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
- query before applying changes --- Check this mark to make the element show a query before a parameter gets actually commanded.
- query text --- The query text to be shown in the pop-up window. you may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set.
- use spin buttons --- Checking this mark enables "spin buttons" for numeric entry fields. Clicking these small arrow symbols at the right edge of the entry field increases/decreases the value by a certain amount. clicking them with the right mouse button increases/decreases by a larger amount.Enabling spin buttons with automatic step size automatically enables the "use editable drop down list" feature.
- fixed step size --- Checking this mark permits to set user defined increment values for the spin buttons. If not checked, the spin button increment is derived from the least significant digit shown in the field, the large (right mouse button) increment is ten time that.
- small steps --- The spin button increment value to be applied with left mouse button clicks.
- large steps --- The right mouse button spin button increment. The program assumes 10 times the small steps if the large steps field is left empty.
- use editable drop down list / force single click select --- Checking this mark changes the type of drop down list to be used with a choice parameter.Enumerated values normally are shown as a drop down list which pops up if you click into the field. This element type is not keyboard sensitive, you always have to select the value with the mouse which may be inconvenient if the list contains a large number of values.With the editable drop down list option checked you can type into the field and write some characters of the new value you want to set. The element pops up a list of applicable setting containing the typed characters. Clicking to the selected value in the list completes the selection, sets the value.If the widget is configured for a height of 40 pixels or more, it appears as a scrollable list rather than as a drop down box. Checking this mark forces the widget to select a value with a single mouse click, normally a double click is required to select a value.Selecting this option automatically enables "use spin buttons".
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable

addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.

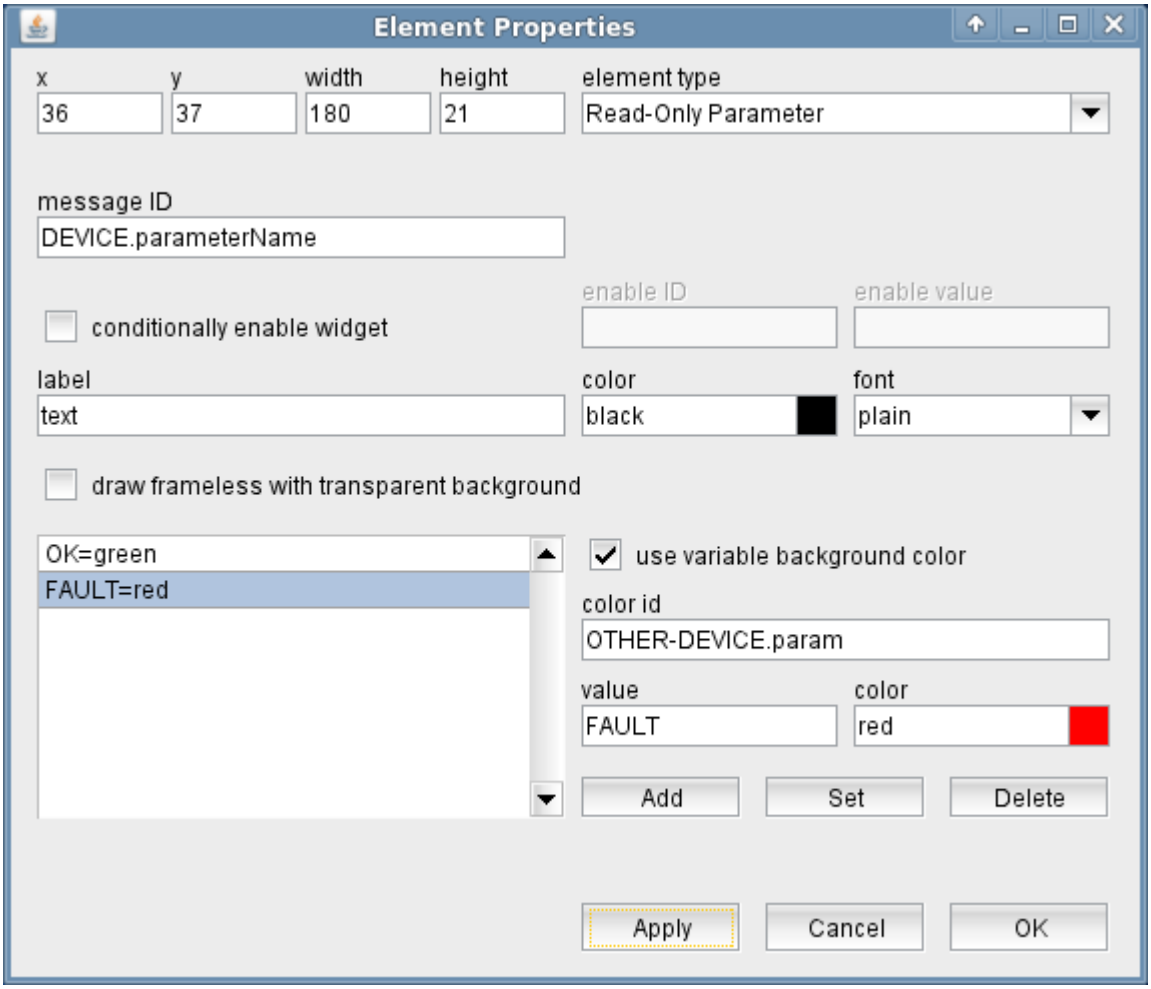
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
  - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
  - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
  - To delete a value / color pair from the list, select the table entry and then click "Delete".

Remarks

- The options "use spin buttons" (automatic step size) and "use editable drop down list" internally use the same use the same property of the screen element. Hence, these options are linked in way that if you enable one of these options, the other one is selected as well. This is done to maintain compatibility to older versions of the software. This linkage means no limitation, as a parameter element never can be a numeric entry field and a choice list at the same time.
- The predefined screens of the software always use the "plain" font and a height of 21 pixels for parameter fields.
- If you enlarge the height for a choice parameter widget to more than 40 pixels, the software uses a list widget with scroll bars rather than a drop down selection box.
- If you enlarge the height for a entry field to more than 50 pixels, the software uses a multi line entry field widget. Multi line entry fields are useful only for very few types of parameters, they are not recommended for general use.

3.16.2.4.2 Read-Only Parameter

The *Read-Only Parameter* display element is used to display M&C parameters read-only. It looks much alike the Parameter element, but never allows to change the parameter it displays.



The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses the parameter the element shall display or edit. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the ' Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- color --- The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
- draw frameless with transparent background --- Check this mark to let the software draw the element without a entry field frame and with transparent background. With this option the Read-Only-Parameter element can be used as a label which changes it's text with the value of a variable. Please note that you cannot use the 'variable background

color' option (described below) together with the frameless / transparent background option.
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
    - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
    - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
    - To delete a value / color pair from the list, select the table entry and then click "Delete".

Remarks

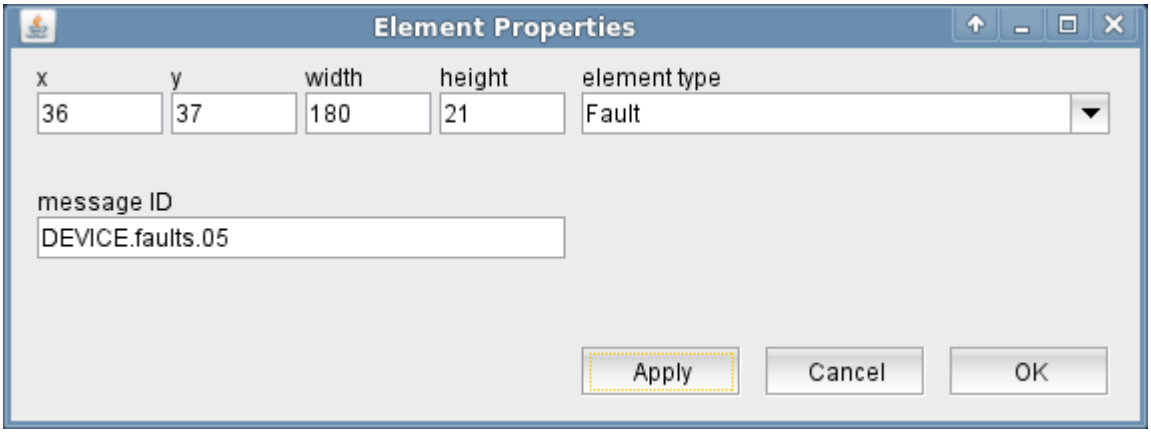
- The predefined screens of the software always use the "plain" font and a height of 21 pixels for parameter fields.

3.16.2.4.3 Fault

The *Fault* display element shows a fault flag. The faults page of the predefined device windows makes use of this display element.

The software treats device faults in a special way. In the variable list of a device driver the fault flags appear as variables called "faults.00" .. "faults.99". The software automatically produces a variable "config.faults.XX" for each fault flag "faults.XX" the driver defines. This configuration variable controls the priority of the fault. The Fault display element now:

- Displays the state if the fault flag (OK/FAULT)
- Displays the fault text (the description for the fault flag is distributed as a message at runtime).
- While the operator holds down the left mouse button on it, the Fault element shows the priority set for this fault.
- With the right mouse button the Fault element shows a context menu to change the fault's priority.

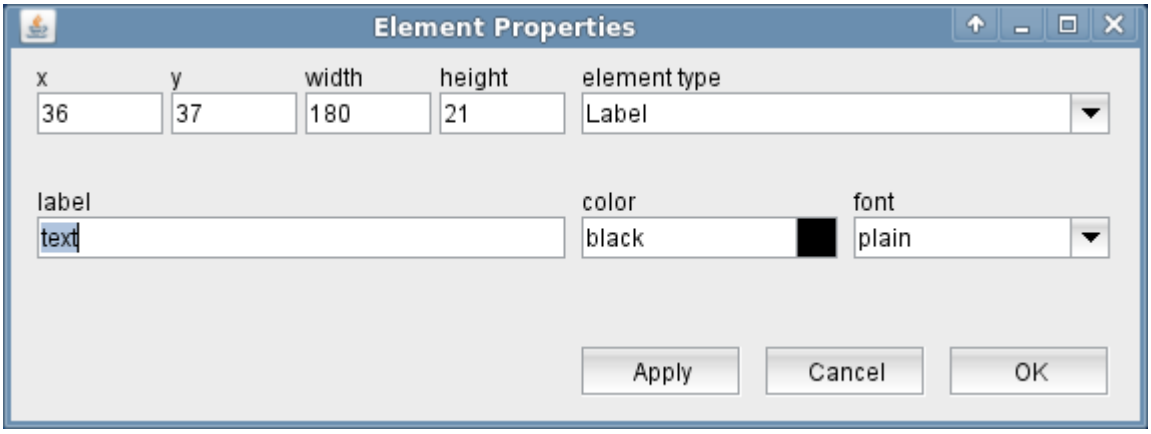


The attributes listed below may be configured to customize a display element of this type:

- Message ID --- The message ID addresses the parameter the element shall display or edit. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.faults.22* for example addresses the variable *faults.22* at a device named *XMIT-1* . With the 'Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.

3.16.2.4.4 Label

The *Label* display element shows a label (a one line text string) with a selectable font / color.

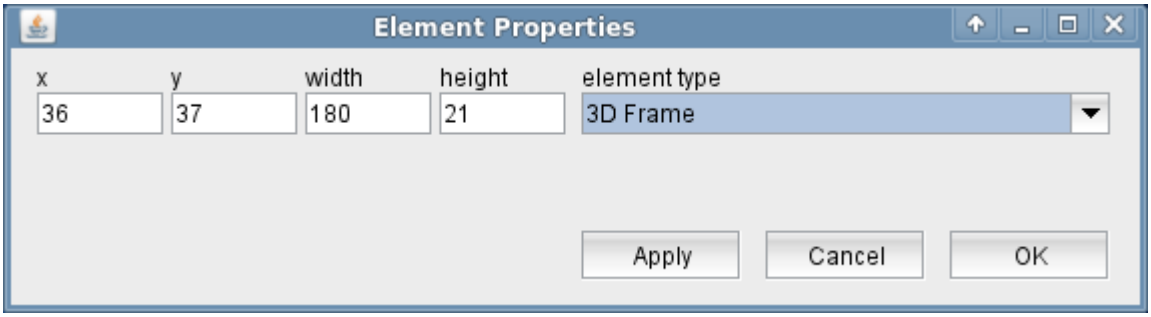


The attributes listed below may be configured to customize a display element of this type:

- text --- The text to be shown.
- color --- The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font to be used for the label.

3.16.2.4.5 3D Frame

The *3D Frame* display element draws a sunken 3D frame, which is intended to be used to group other elements.



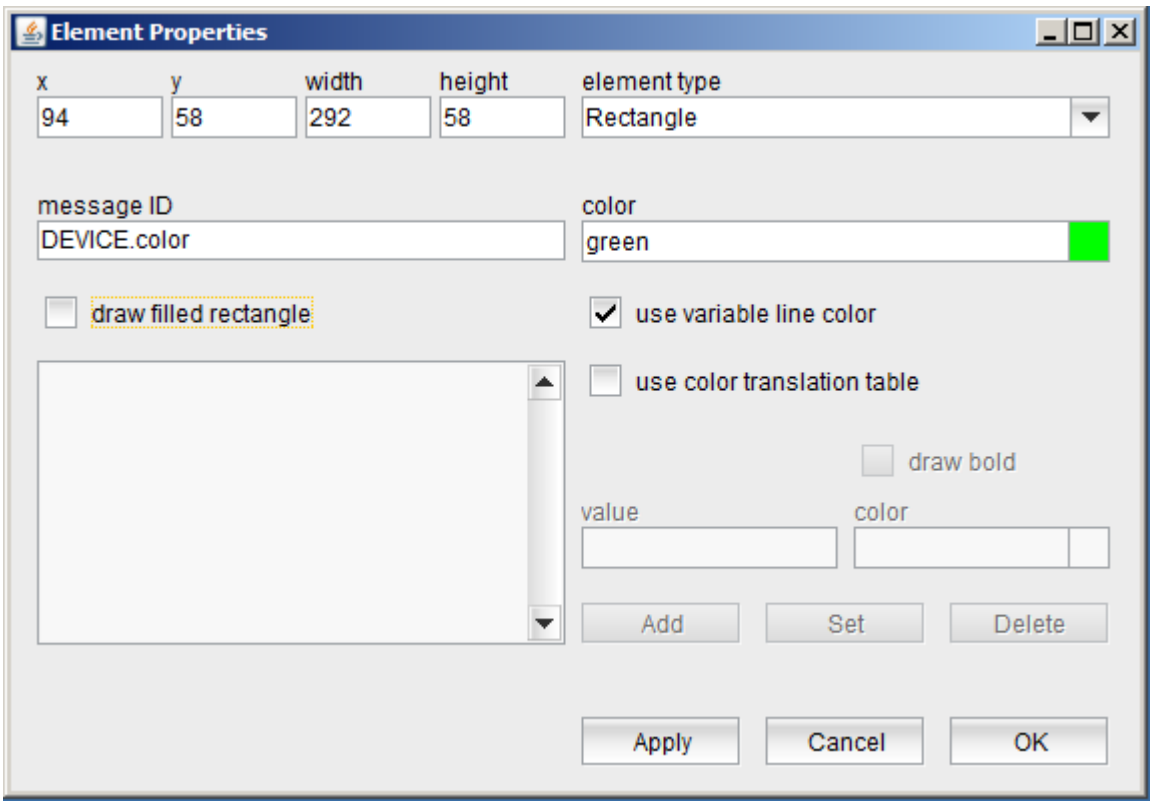
Beside the position in the window there are no user configurable attributes to set.

Remarks

The 3D frame's inside area is transparent, it does not conceal the screen elements it encloses. In the screen editor, however the 3D frame grabs all mouse clicks, so you might not be able to mode the elements which are inside the frame. In this case move the 3D frame to the back by pressing while the frame element is selected. The other elements are now "on top" of the frame element and may be addressed by the mouse independently.

3.16.2.4.6 Rectangle

The *Rectangle* display element draws a rectangle with a selectable color.



The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses a parameter which controls the color of the rectangle. No message ID is required if the rectangle shall be drawn with a fixed color.
- color --- The color to be used to draw the rectangle unless a variable line color is specified. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- draw filled rectangle --- If this mark is checked, a solid rectangle is drawn. The 'draw bold' property in the color translation table has no effect when the rectangle is drawn solid.
- use variable line color --- Check this mark to let the software draw the rectangle with a color specified by the value of the variable specified by 'message ID'. Unless you check the mark 'use color translation table', the software interprest the variable contents as described below in the paragraph 'Color / Line Width Codes'.
- use color translation table --- Checking this mark enables a color translation table which works much like the variable background color feature for entry elements. Depending on the actual value of the variable addressed by 'message ID', the element's line color and thickness is set using the translation table shown in the lower left corner of the dialog. If the actual value of the variable does not match any of the table entries or if no message ID is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- draw bold --- The line thickness specification of the actually selected table entry. If the mark is checked, the line is drawn 3 pixels wide, with the mark unchecked the line width is 1 pixel.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
    - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
    - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
    - To delete a value / color pair from the list, select the table entry and then click "Delete".

Color / Line Width Codes

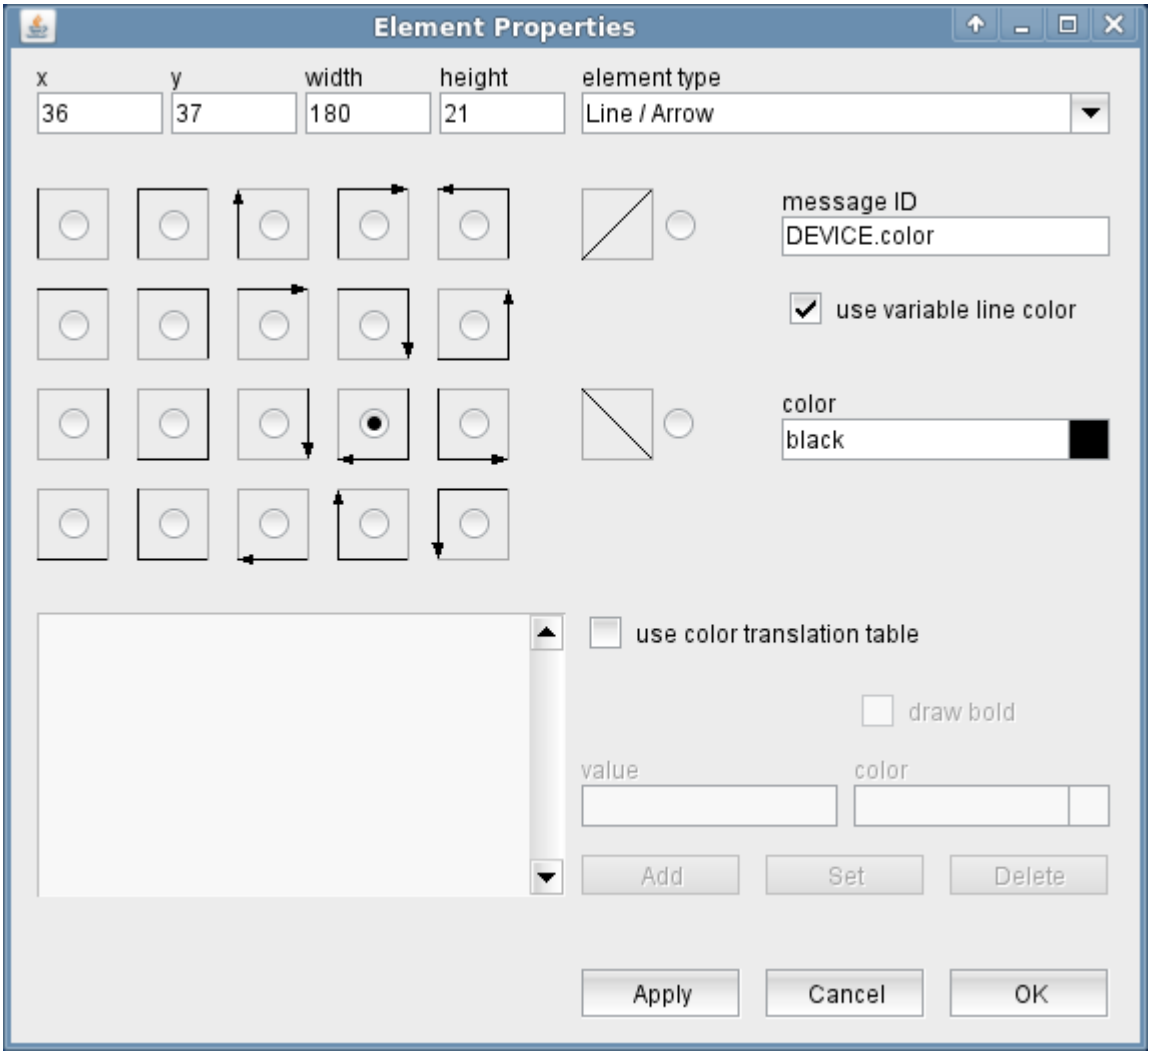
If you check the 'use variable line color' mark without using a color translation table, the software interprets the variable contents as a text value and parses it using the following rules (upper/lower case doesn't matter):

- If the variable value starts with one of the keywords BLACK, WHITE, RED, GREEN, BLUE, YELLOW or GRAY, this color is used.
- If the variable value ends with BOLD, the line is drawn 3 pixels wide (instead of 1 pixel default width).
- If the variable value is TRUE or it contains the text FAULT, the line is drawn red, 3 pixels wide if the variable denotes a fault flag.
- If the variable value is TRUE and the variable does not denote a fault flag, the line is drawn green, 3 pixels wide.
- If the variable value is ON, the line is drawn green, 3 pixels wide.
- If the variable value starts with a '#' character, the following six characters are interpreted as a hexadecimal number, specifying the RGB parts of an arbitrary color. Example: "#FF00FF-BOLD" defines a 3 pixels wide, magenta colored line.
- If none of the rules above matches, the line is drawn with the default color, 1 pixel wide.

The ' Gate-Array ' logical device may be used to combine several state variables in the M&C and generate the color codes expected by the line / arrow element.

3.16.2.4.7 Line / Arrow

The *Line / Arrow* display element draws a horizontal and/or a vertical line and optionally an arrowhead. The line's color is selectable. Strictly speaking the Line / Arrow element is a rectangle with only one or two sides drawn.



The attributes listed below may be configured to customize a display element of this type:

- shape --- To select which parts of the bounding rectangle of the element shall be drawn as a line, select one of the shape symbols.
- message ID --- The message ID addresses a parameter which controls the color of the rectangle. No message ID is required if the rectangle shall be drawn with a fixed color.
- use variable line color --- Check this mark to let the software draw the rectangle with a color specified by the value of the variable specified by 'message ID'. Unless you check the mark 'use color translation table', the software interprest the variable contents as described below in the paragraph 'Color / Line Width Codes'.
- color --- The color to be used to draw the rectangle unless a variable line color is specified. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- use color translation table --- Checking this mark enables a color translation table which works much like the variable background color feature for entry elements. Depending on the actual value of the variable addressed by 'message ID', the element's line color and

thickness is set using the translation table shown in the lower left corner of the dialog. If the actual value of the variable does not match any of the table entries or if no message ID is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.

- draw bold --- The line thickness specification of the actually selected table entry. If the mark is checked, the line is drawn 3 pixels wide, with the mark unchecked the line width is 1 pixel.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
  - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
  - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
  - To delete a value / color pair from the list, select the table entry and then click "Delete".

Color / Line Width Codes

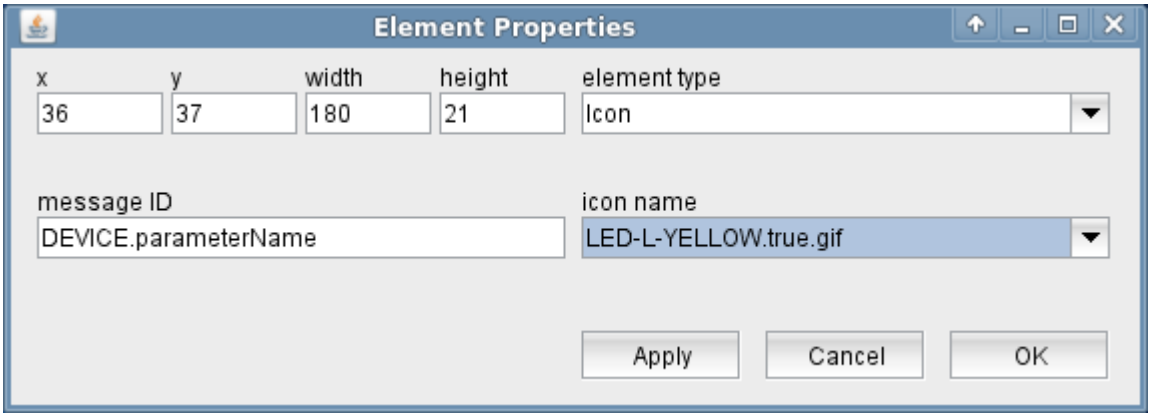
If you check the 'use variable line color' mark without using a color translation table, the software interprets the variable contents as a text value and parses it using the following rules (upper/lower case doesn't matter):

- If the variable value starts with one of the keywords BLACK, WHITE, RED, GREEN, BLUE, YELLOW or GRAY, this color is used.
- If the variable value ends with BOLD, the line is drawn 3 pixels wide (instead of 1 pixel default width).
- If the variable value is TRUE or it contains the text FAULT, the line is drawn red, 3 pixels wide if the variable denotes a fault flag.
- If the variable value is TRUE and the variable does not denote a fault flag, the line is drawn green, 3 pixels wide.
- If the variable value is ON, the line is drawn green, 3 pixels wide.
- If the variable value starts with a '#' character, the following six characters are interpreted as a hexadecimal number, specifying the RGB parts of an arbitrary color. Example: "#FF00FF-BOLD" defines a 3 pixels wide, magenta colored line.
- If none of the rules above matches, the line is drawn with the default color, 1 pixel wide.

The ' Gate-Array ' logical device may be used to combine several state variables in the M&C and generate the color codes expected by the line / arrow element.

3.16.2.4.8 Icon

The *Icon* display element shows an arbitrary GIF/JPEG picture. The image file must reside in the *./images* directory on the M&C/NMS server.



The attributes listed below may be configured to customize a display element of this type:

- message ID --- You can make the image change with a parameter value. The message ID addresses the parameter which selects the image to display (see below for details). The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the ' Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- icon name --- Selects the name of the image to display.

Using an icon to display a parameter

If you specify a message ID with the element properties of an *Icon* , the image displayed will change with the parameter value addressed by the message identifier.

You must supply one image file for each value the parameter may have. The parameter value must appear in the file name just in front of the gif/jpg suffix, enclosed in dots. All images used for one parameter should be of the same size. If the *Icon* element receives a parameter value it does not find an image file for, a black rectangle is displayed instead of an image.

Example: Let's assume you want to visualize a TX ON/OFF switch with an antenna symbol changing it's color with the position of the switch. Supply two images called "transmission.ON.gif" and "transmission.OFF.gif" which symbolize these states as you want. Notice that the ON/OFF keywords in the file names *exactly* reflect the possible values of this parameter and that the file names only differ in this point. Select one of image files for the icon element and enter the message Id of the TX-ON/OFF parameter into the appropriate field.

The mechanism used to select the image file to display mostly limits the usage of dynamically changing icons to CHOICE parameters. Merely numeric (integer) parameters with a very limited number of possible values come into question, too.

Using an icon to display a device summary fault

With device summary faults ("DEVNAME.fault"), and subsystem faults ("SUBSYSTEM. ... .fault")

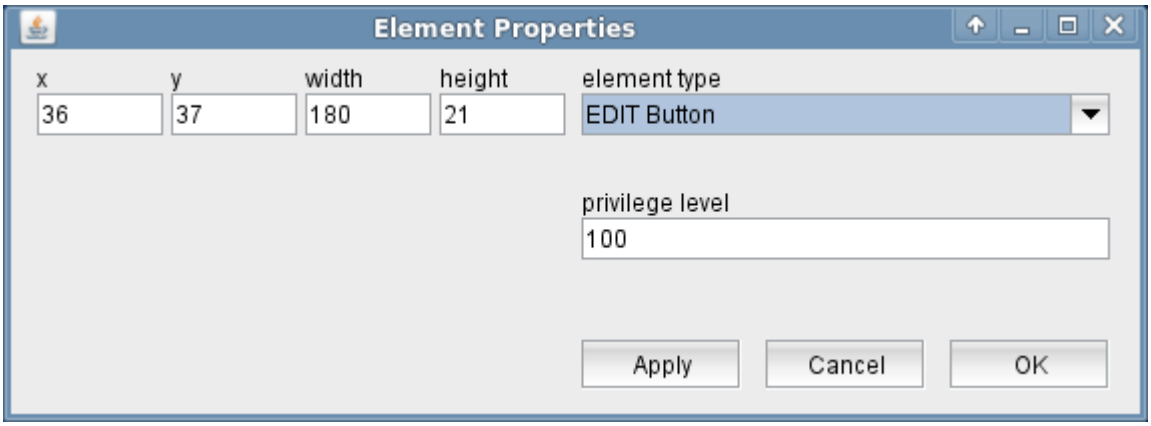
the *Icon* element translates the fault state to "true" for FAULT and "false" for "OK.". This is because the sat-nms software provides the individual fault flags in a device driver as boolean values, the summary fault however is represented by a text which can be one of "OK.", "WARNING" and "Summary FAULT". Translating the OK/FAULT values lets you use the same image files for individual and summary fault states.

To display a device summary fault as an color changing icon, you have to provide three image files, for example:

MyIcon.false.gif for the "OK" state **MyIcon.WARNING.gif** for the "WARNING" state **MyIcon.true.gif** for the "FAULT" state

3.16.2.4.9 EDIT Button

The *EDIT Button* display element places an EDIT button to the screen. It appears as a simple button with the label "EDIT" on it. You define one (and only one) EDIT button in a screen which shall be operated following the EDIT / TAKE operating method explained below. If you have an EDIT button in a screen you must have e TAKE button , too.



The attributes listed below may be configured to customize a display element of this type:

- privilege level --- With this attribute you specify the minimum privilege level an operator must own in order to be permitted to press this button.

The EDIT / TAKE operating method

The M&C software uses the same display elements to show the values read from a device (monitoring) and to change parameter settings on an operator's request (control). The operating situation determines whether a display element contains a monitored value or an edited one.

The software usually changes each parameter as you edit it. More precisely, if you edit a value in an entry field, the field's background becomes yellow to point out that the value is an edited one. If you leave the field or if you press RETURN, the edited value is sent to the device. CHOICE parameters behave slightly different, but in a similar sense.

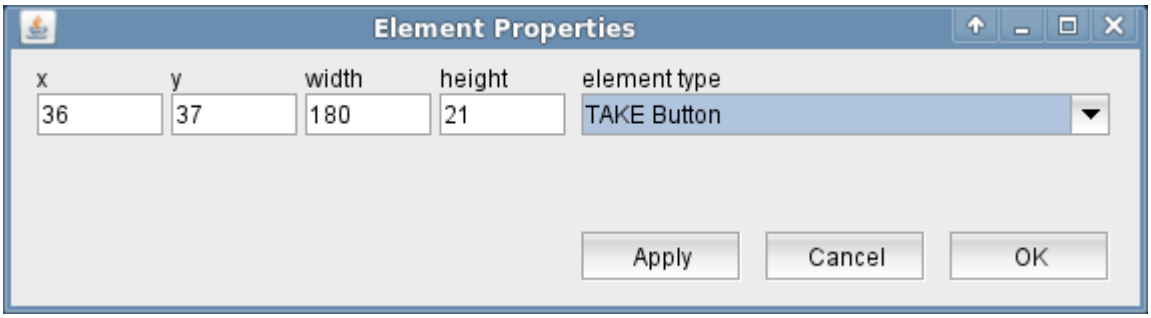
Now, if an EDIT button is defined in the screen, it behaves completely different. All display

elements in the screen show the values monitored at the device in the default state of the screen. You can't change any parameter in this state unless you press the EDIT button. With the EDIT button pressed (it's a latching one) the screen turns into "edit" state and stops updating the screen elements with the values monitored from the device. Now you can change the parameter values, however a changes value will not be sent to the device unless you press the TAKE button. When doing so, all parameter values from this screen are sent to the device at one time. The screen returns to the default state in order to show the values read back from the device.

Using the EDIT / TAKE operating method disables the "intelligent" change parameter ranges, some device drivers support. A modem device driver may dynamically change the valid range of the symbol rate depending of the FEC actually selected. With the EDIT / TAKE operating method, the device driver does not receive the FEC setting as you edit it and therefore cannot change the symbol rate range accordingly. For this reason you should use the EDIT / TAKE operating method only where this is a strong requirement for some reason, not as the default operating style for all screens.

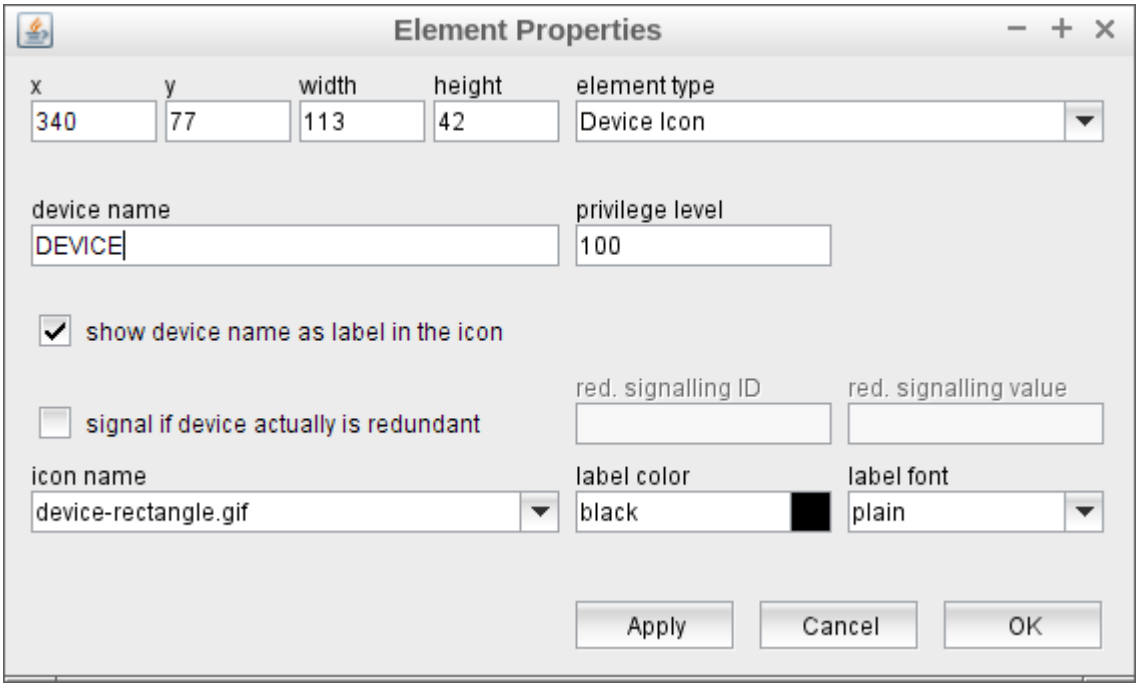
3.16.2.4.10 TAKE Button

The *TAKE Button* display element places an TAKE button to the screen. It appears as a simple button with the label "TAKE" on it. The TAKE button complements the EDIT button described above in this document. It sends the changed parameter values to their destination when pressed. A detailed description of the EDIT / TAKE operating method for M&C screens is given at the EDIT Button chapter.



3.16.2.4.11 Device Icon

The *Device Icon* display element represents a device in the M&C user interface. It displays the status of the device by it's color/shape and gives access to the Device Window for this particular device by a double mouse click. The right mouse button launches a context menu with common operations for the device.



The attributes listed below may be configured to customize a display element of this type:

- device name --- The name of the device this element stands for.
- privilege level --- The privilege level necessary to use this device icon. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to use this icon.
- show device name as label in the icon --- Check this mark to show name of the device as a label in the icon. Un checking may be useful when using very small icons where the label would not fit inside or when a label shall be used which differs from the name of the device.
- signal if device actually is redundant --- Check this mark to apply a special coloring for devices which are in the redundant signal path of a redundancy switching facility.
- red. signalling ID --- The message ID of a parameter which gives the information if the device actually operates as the redundant one or if it is operational. For a 1:1 TWTA redundancy this could be the position parameter of the waveguide switch which selects the signal from the two TWTAs
- red.singalling value --- If the value of the parameter addressed by above message ID matches the value given in this field, the device icon is shown as "redundant" (depends in the icon set used, the factory icon sets use a blue background color for this).
- icon name --- Selects the name of the image to display. The sat-nms software at least provides three predefined icons for this purpose:
  -  --- device-rectangle.gif
  - --- device-square.gif
  - --- device-minirect.gif

Your installation probably will contain some more device icons to select.

- label color --- The color attribute of a parameter element sets the color of the device name shown with the icon.
- label font --- The font attribute applies to the device name, too.

Using customized images

You may supply your own images for the device icon display element. To do so, place seven images into the *./images* directory named "xxxxx.gif", "xxxxx-F.gif" (fault), "xxxxx-C.gif" (communication fault), "xxxxx-S.gif (fault suppressed)", "xxxxx-R.gif" (redundant), "xxxxx-O.gif" (out of service) and "xxxxx-M.gif" (maintenance). You should consider the following:

- All images should be of the same size.
- The software places the device name at the lower left corner of the image using the selected font and color. All four images should use appropriate colors in this area to keep the device name visible.
- Beside GIF-images the software also accepts PNG images (file extension .png) and JPG images (file extension .jpg). All images of a set must be of the same type (GIF/PNG/JPG).

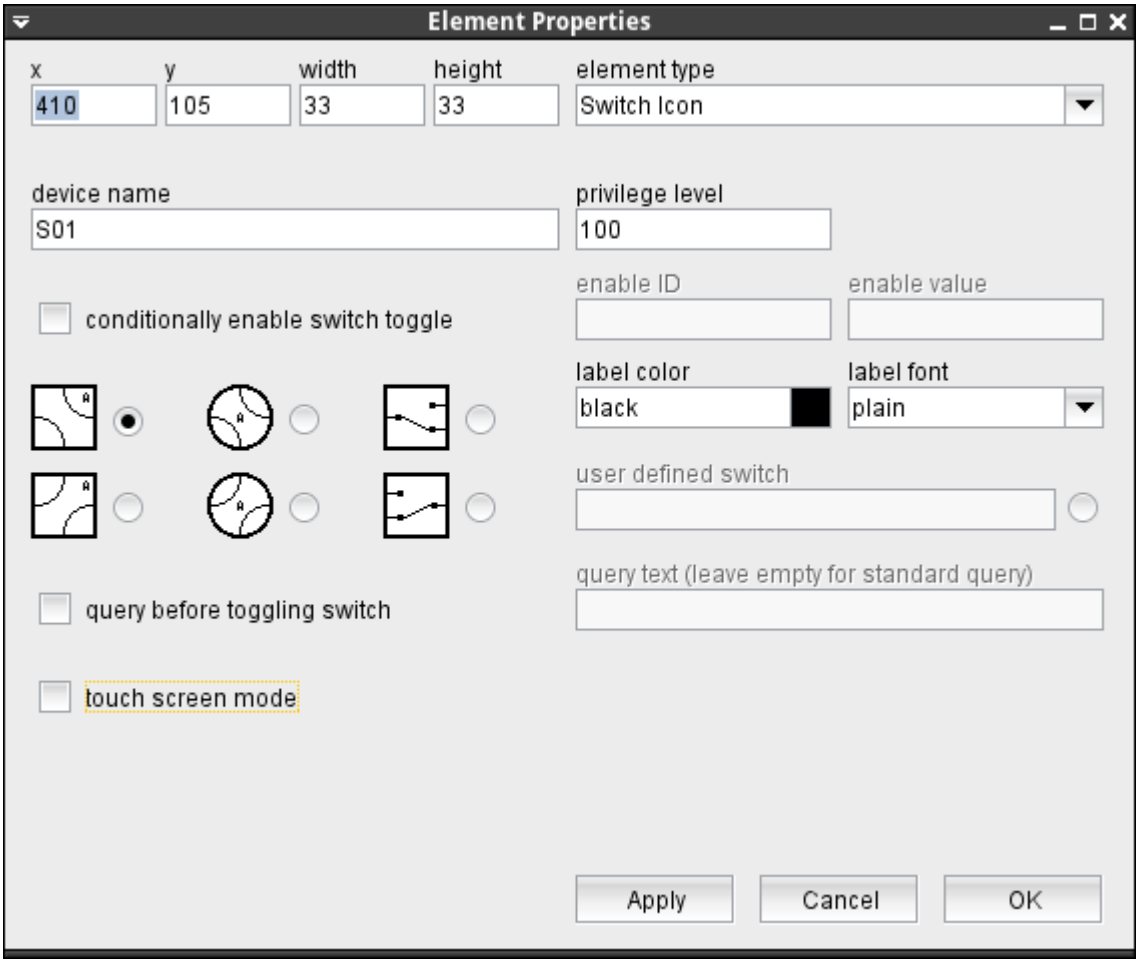
Using a customized 'transmitting' emblem

For devices which provide the 'info.signal.on' parameter to report that the device is actually transmitting or receiving, the device icon shows an emblem at it's upper right corner. The software uses the 'signal-on-emblem.png' image as a default for this.

You may define individual emblems for each image set by placing a "xxxxx-X.gif" (or .png/.jpg) image in the ./images folder with xxxxx being the base name of the device icon. The software will use this file for the transmitting emblem of this particular icon set. The file extension of the emblem must match the extension of the base icon image.

3.16.2.4.12 Switch Icon

The *Switch Icon* display element is a special version of the Device Icon element which may be used to visualize the position of a switch in a user interface screen designed as a block diagram. The switch icon has all capabilities of a plain device icon display element. The context menu shown with this right mouse button additionally contains an option to toggle the switch position. The switch icon element -- unlike the plain device icon element -- does *not* support user defined images.



The attributes listed below may be configured to customize a display element of this type:

- device name --- The name of the device this element stands for. You also may enter the complete ID of the parameter which controls the switch position for devices which manage more than one switch or use a non-standard switch position parameter name.
- privilege level --- The privilege level necessary to toggle the switch position. To change the device mode (OPERATIONAL, OUT-OF-SERVICE), at least a privilege of 100 is necessary, or the value set here if this is higher.
- conditionally enable switch toggle --- The toggle function of a switch icon may be locked unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.
- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" must match this value in order to enable the toggle option of the switch icon.
- shape --- Select the shape of the icon from the given switch symbols or a user defined switch. .ts user defined switchThe (base-) name of a set of userdefined switch icons. See below how to use your own switch icons.
- label color --- The color attribute of a parameter element sets the color of the device name shown with the icon.

- label font --- The font attribute applies to the device name, too.
- query before toggling switch --- Check this mark to make the element show a query before a switch toggle gets executed.
- query text --- The query text to be shown in the pop-up window. you may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set.
- touch screen mode --- Selecting this option makes the switch icon behave differently, optimized for touch screen usage. You may toggle the switch position by touching the icon twice. This first time you touch it, the icon shows a turquoise ball in the upper left corner. This ball disappears after 2 seconds. If you touch the icon a second time before the turquoise ball disappears, the switch is actuated.There is no right mouse button context menu in this mode, no way to go into the device screen or set the device OUT-OF-SERVICE.

Remarks

Configuring a confirmation question as described above, only affects the 'Toggle position' function provided by the switch icon's right mouse context menu. Setting the switch position from the device dialog always works without a confirmation request.

User defined switch icons

The sat-nms software comes with 6 predefined switch icons. You may add your own icons if none of the predefined switches matches your needs.

For a user defined switch you have to create a set of ten PNG image files / icons. Each icon shows one combination of switch position and device state. All icons of a set must be of the same size, the files must be located in the *images* subdirectory of the sat-nms server installation and they must follow the naming scheme described below.

The file name of a switch icon consists of the user defined name, follwed by a dash and a 2-character status code. All switch icons must be PNG images and end with the file suffix ".png" (lower case). The first character of the status code reflects the switch position, the second one the device's fault/operation state. The following codes are defined:

pos.	***character***	***description***
1	A	switch is in position A (or OFF)
1	B	switch is in position B (or ON)
2	N	switch device is in normal operation, no fault is pending
2	W	switch device shows a warning
2	F	switch device shows a fault

pos.	*character*	*description*
2	S	switch device is set FAULT-SUPPRESSED
2	O	switch device is set OUT-OF-SERVICE

Combining the two switch positions with five device status codes results in totally 10 icons which show all possible states of a switch. If you create a switch named "myswitch", the files would be:

myswitch-AN.png myswitch-AW.png myswitch-AF.png myswitch-AS.png myswitch-AO.png myswitch-BN.png myswitch-BW.png myswitch-BF.png myswitch-BS.png myswitch-BO.png

Replacing the predefined icons

In in your sat-nms installation mostly user defined switch symbols are used, you may replace some or all of the predefined switch symbols offered by the Switch Icon dialog with your favorite icons. To configure this, edit the file "client.properties" in the base directory of the sat-nms server installation and add some or all lines of the following:

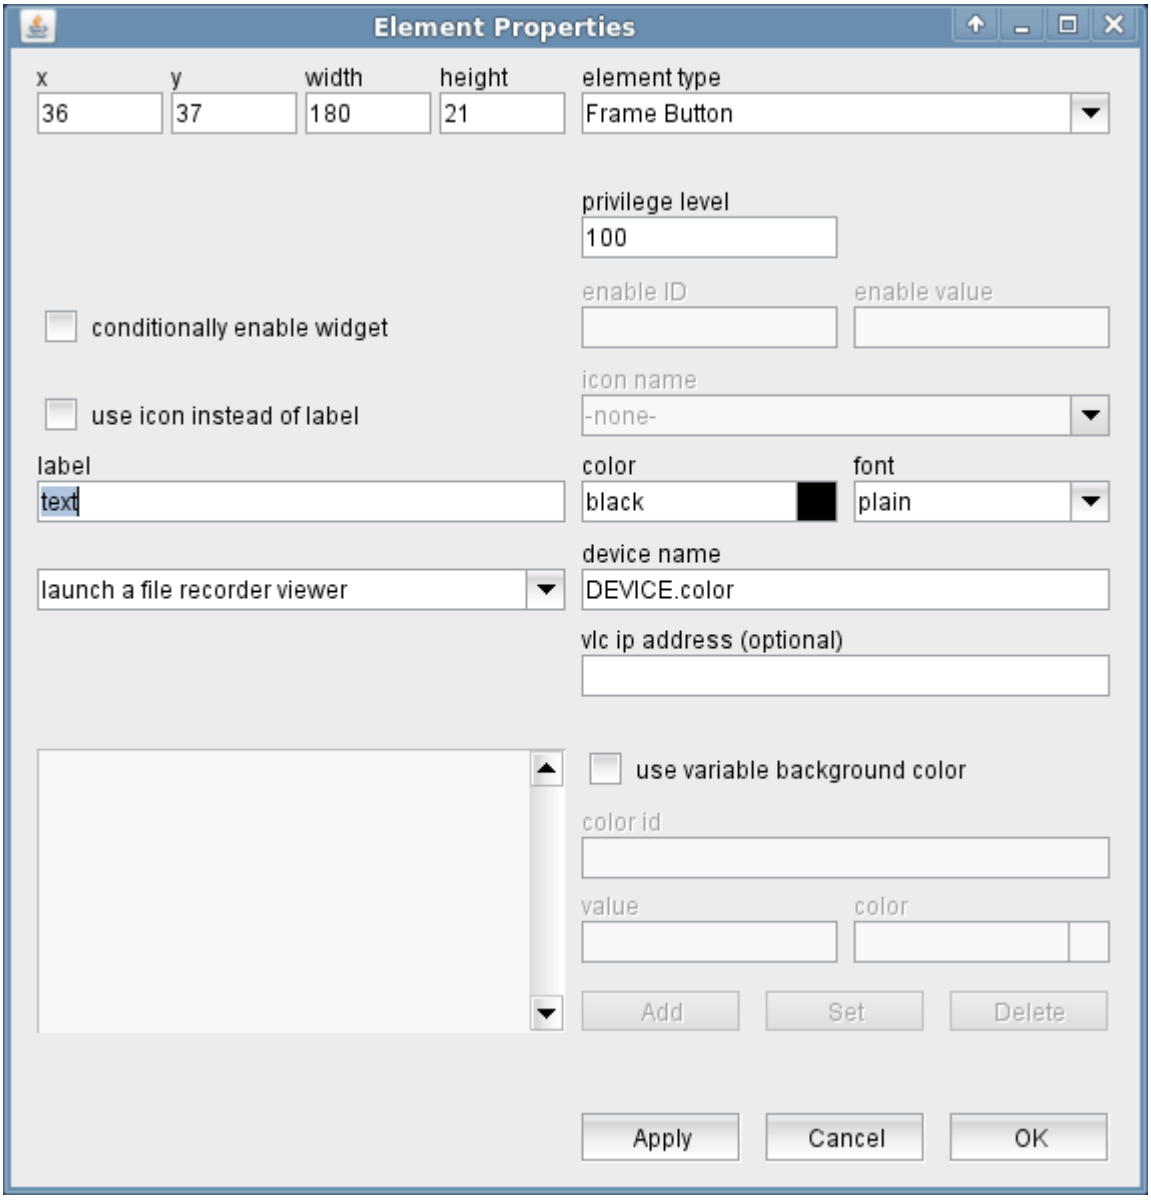
gui.editor.predefinedSwitch.1=myswitch1 (replace myswitch1 by the name of the icon set to use) **gui.editor.predefinedSwitch.2=myswitch2 gui.editor.predefinedSwitch.3=myswitch3 gui.editor.predefinedSwitch.4=myswitch4 gui.editor.predefinedSwitch.5=myswitch5 gui.editor.predefinedSwitch.6=myswitch6**

Please note, this does not replace / delete the factory icons. Screens which make use of the factory switches will still use them as before and you are still able to edit screens with factory switch icons by explicitly define their names in the *user defined switch* field. The names of the factory switch icons are *wgswitch* , *wgswitch-mirrored* , *cxswitch* , *cxswitch-mirrored* , *lswitch* and *rswitch* .

User defined switch icons may be of any size, even larger than the factory icons. When used as predefined switch icons, such large icons will show up in the dialog with their upper left corner only. In the screen the icons gets displayed with it's full size.

3.16.2.4.13 Frame Button

The *Frame Button* display element creates a button which launches another user interface screen if pressed. The screen to be launched may be another user defined screen or a predefined one.



The attributes listed below may be configured to customize a display element of this type:

- privilege level --- The privilege level necessary to activate this button. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- FRame buttons may be locked to disabled state unless another parameter matches a given value. Check this mark to activate this feature.
- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the entry field.
- use icon instead or label --- Check this mark in order to make the button show an icon instead of a label text.
- icon name --- Provides a list of all available icons / images on the sat-nms server.
- font --- The font to be used for the button label.

- label --- The label text is drawn on the button.
- color --- The color of the button label. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font of the button label.
- button function --- with this field you select the function of the button. The available functions are listed below. The meaning of the parameters right beside the function selector changes with the function selected.
- *launch a child screen* --- Launches a new screen in a separate window. Parameter 1: screen name Parameter 2: n/a
- *replacescreenwithanotherone* --- Replaces the actual screen by another one, re-uses the same window. Parameter 1: screen name Parameter 2: n/a
- *launch a tty setup window* --- Launches a dialog to edit the line settings of a serial interface. Parameter 1: interface name, e.g. ttyS2 Parameter 2: n/a
- *launch a device setup window* --- Launches a dialog to edit the setup parameters of a given device. Parameter 1: name of the device Parameter 2: n/a
- *launch a load preset dialog* --- Launches a dialog to select and apply a preset to a given device. Parameter 1: must contain the name of the device, followed by a comma and the name of the device driver used by the device. Example: MODEM-1,Comstream-CM601A-SCPC Parameter 2: if this parameter is not empty, the preset load dialog initializes it's search pattern field with this value. Only presets containing the pattern string (character case doesn't matter) will appear in the list.
- *launch a text viewer window* --- Launches a multiline text view window which shows the actual contents of the given parameter. Parameter 1: The message ID of the parameter to show. Parameter 2: n/a
- *launch a tracking viewer* --- Launches a tracking report window for the Antenna-Tracking logical device. The tracking report window shows azimuth or elevation together with the beacon level over the recent 48 hours. Parameter 1: The message ID to show. Typically this is the "state.mode4" Parameter of an Antenna-Tracking or a SatService-ACU-ODM device. Parameter 2: n/a
- *launch a az/el viewer* --- This is much like the tracking viewer, but the window plots elevation versus azimuth in a quadratic diagram. Parameter 1: The message ID to show. Typically this is the "state.mode4" Parameter of an Antenna-Tracking or a SatService-ACU-ODM device. Parameter 2: n/a
- *launch a file recorder viewer* --- Launches a graphical presentation screen for data recorded with a File-Recorder logical device. Parameter 1: Name of the File-Recorder device and (optionally) a preset number 1..8 to be invoked after the data has been loaded. A ">" may be appended to the preset number in order to make the diagram show recent data instead of the data shown at the time when the preset was stored. Example: "FILEREC-12>" shows the dat a of the FILEREC-1 device, invokes the preset number 2 and shows the data recently recorded by the file recorder device. Parameter 2: In an NMS environment you must supply the VLC's IP address in this field. The VLC must be reachable directly and permanently from the client PC to make this feature work safely. In a M&C system leave the field empty
- *launch a spectrum viewer* --- Launches the device window of a spectrum analyzer and optionally sets an arbitrary number of parameters. Parameter 1: The name of the

spectrum analyzer device Parameter 2: An optional macro list. This may contain zero or more parameter ID - value pairs. These settings may be used to preset the spectrum analyzer certain settings but also to control switches or other devices in the signal path. Example: S03=B, SA1.center=12345.666 If the operator clicks to this button, the switch S03 is commanded to position B, the spectrum analyzer SA1 is set for a center frequency of 12345.666 MHz and the spectrum analyzer window gets opened.

- *launch an m&c client* --- Launches another M&C client program which connects to the given IP address. The M&C client runs in a separate JVM. It tries to login at the target machine with the same name and password the parent program uses. Parameter 1: The address to connect to Parameter 2: n/a
- *launch another java runtime* --- Runs an arbitrary Java program by starting another JRE process. Note, that all command line arguments including the classpath specification must be provided. These arguments probably will be platform specific, hence a user interface depending on this feature only will work on the platform it is configured for. Parameter 1: The command line parameter for the java program Parameter 2: n/a
- *launch a web browser window* --- Launches the platform's standard web browser and shows the given URL. Parameter 1: The URL to show. To show a certain page of the online manual, simply use the 4 digit topic number of the page as the URL parameter. To show an extern web page, e.g. the web based user interface of a sat-nms ACU ODM, enter a URL starting with "http://...". Example: " **http://192.168.2.81** ". Parameter 1 must be a valid URL string in this case, space characters must be escaped as "%20". The BROWSER button this way also can be used to operate a device which provides a web user interface. In device-oriented screens, the character '@' gets expanded to the device's IP address if contained in the URL string. Example: " **http:///** " lets the browser call the top page of the device's web user interface. Parameter 2: n/a
- *start a program on the client pc* --- Starts a program on the client computer. The program must be specified with the full path to the executable file. Parameters for the program may be added, separated space characters. If the path name itself contains space characters, in must be enclosed in double quotes.
- *launch a VideoLAN media player window* --- Starts the VLC media player in a new window to show live video from a certain device. This works with devices like webcams, if the device driver is prepared for this. See the paragraph "VideoLAN media player" below for more details. Parameter 1: The name of the device for which the VLC player shall show the video stream. When used in a device window, parameter 1 is ignored and the button uses the name of the device of this window. Parameter 2: n/a
- *launch a Pointing-Robot import screen* --- Launches a file import window which lets you import pointing table, TLE or Intelsat ephemeris data files from the client PC to the M&C server compunter into the directory where the Pointing-Robot expects these files. Parameter 1: n/a Parameter 2: n/a
- *navigate to a given treeview node* --- Makes the button a navigation button for the treeview application. Clicking the button changes the panel at the right side of the tree view window as if the tree node described by the path specification would have been clicked. Parameter 1: The tree node (path) specification for the button. The path consists of the display names of the tree nodes making up the path to the desired node, separated by '.' characters. If the button for example shall show the page for a subsystem called "Stream-1" contained in a subsystem called "Streams", then the path specification for the button is **Streams.Steam-1** Parameter 2: n/a

- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background. The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
  - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
  - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
  - To delete a value / color pair from the list, select the table entry and then click "Delete".

VideoLAN media player

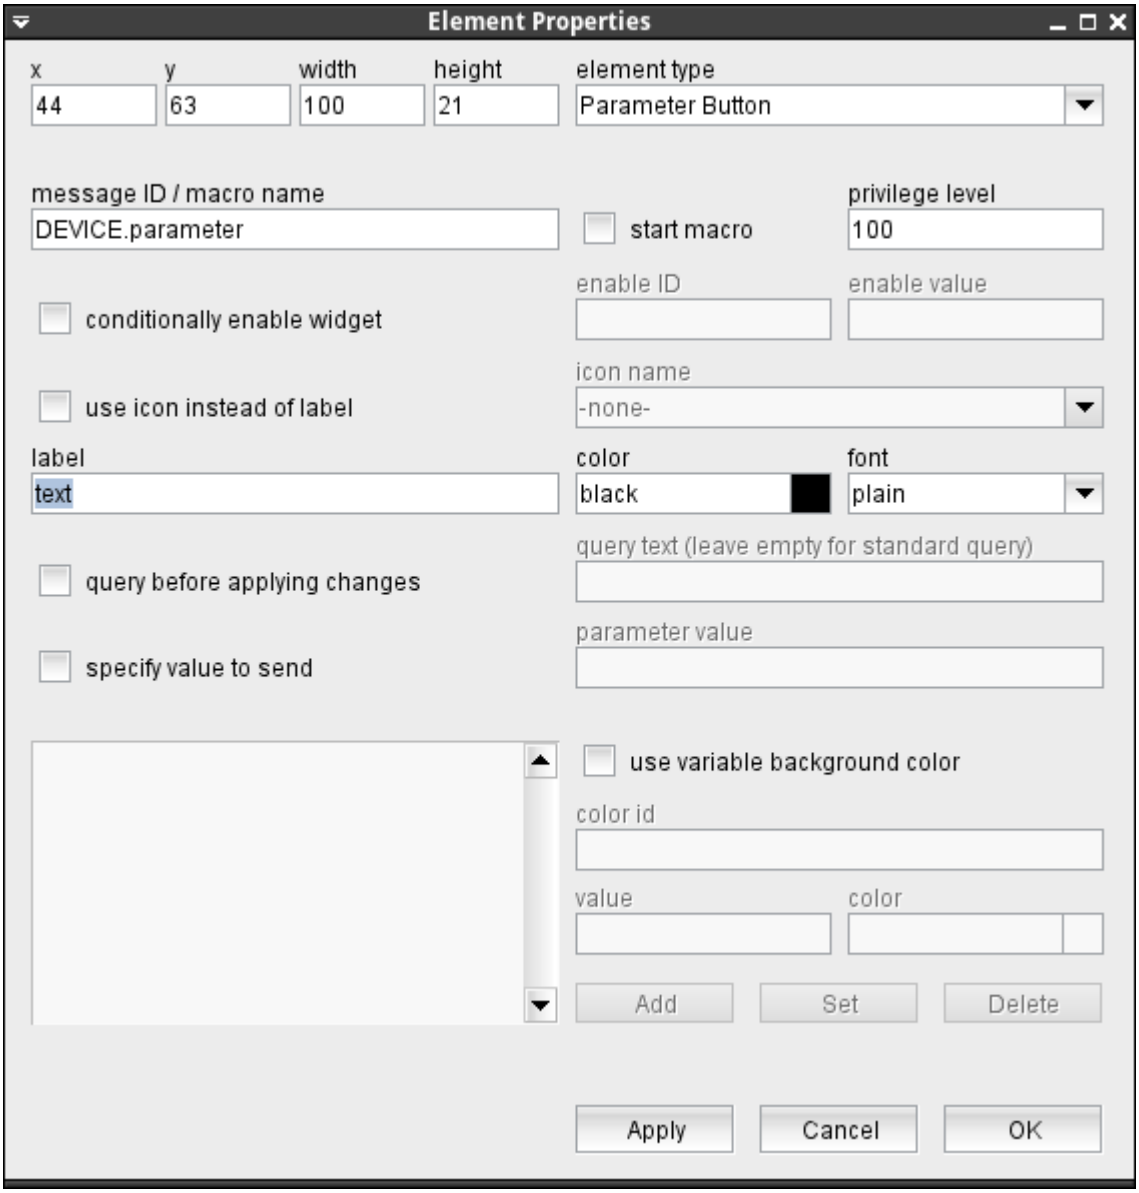
The Frame Button may be configured to launch a VideoLAN media player (VLC) in order to show a live video stream sent by any device capable for this. To use this feature, the VideoLAN media player must be installed on the client machine and the sat-nms driver of the device sending the video stream must be prepared for this.

The frame button expects the device driver to provide a variable called *videoLAN.cmds* which must contain all command line parameters the VLC media player requires to show the desired stream. In the simplest case this is an URL specifying the video stream, but other command line parameters for the VLC player may be used as well.

To launch the VLC media player on Microsoft Windows clients, the program must know the complete path to the executable "vlc.exe". In the M&C server's configuration file 'client.properties' you may set this path. If required, multiple variants may defined, one for each client PC. You find more details on this in the factory default 'client.properties' file.

3.16.2.4.14 Parameter Button

The *Parameter Button* display element is a button which sends a parameter value if pressed. A frequently used application for the parameter button is a RF-OFF button which sends a "tx.on=OFF" to a certain device. Beside this, a parameter button also may be programmed to play a parameter setting macro.



The attributes listed below may be configured to customize a display element of this type:

- message ID / macro name --- The message ID addresses the parameter the button shall control. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable*tx.on* at a device named *XMIT-1* . With the '[Device Driver Index](#) ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.If the "start macro" mark ist checked, this button acts as a macro player button instead of sending a parameter. In this case the field contains the name of the macro to play. If used in an NMS, the macro with this name must be present in the "./macros" subdirectory of the NMS installation.
- start macro --- Selects if the button shall start a macro (checked) or send a certain parameter (unchecked).
- privilege level --- The privilege level necessary to access this button. The predefined screens of the software use 100. In your own screens you may set certain parameters to

higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- Parameter buttons may be locked to disabled state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.
- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the button.
- use icon instead or label --- Check this mark in order to make the button show an icon instead of a label text.
- icon name --- Provides a list of all available icons / images on the sat-nms server.
- label --- The label text is drawn on the button.
- color --- The color of the button label. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font to be used for the button label.
- query before applying changes --- Check this mark to make the element show a query before a parameter gets actually commanded.
- query text --- The query text to be shown in the pop-up window. you may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set.
- specify values to send --- Checking this mark let you define the parameter value to be sent with a button click. Without this option the button sends the label text as a parameter value.
- parameter value --- The value to be sent when the button is clicked.
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
    - To add a new value / color pair to the list, fill the value and color fields, then click to

"Add".
- To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
- To delete a value / color pair from the list, select the table entry and then click "Delete".

Using the Parameter Button to control device presets

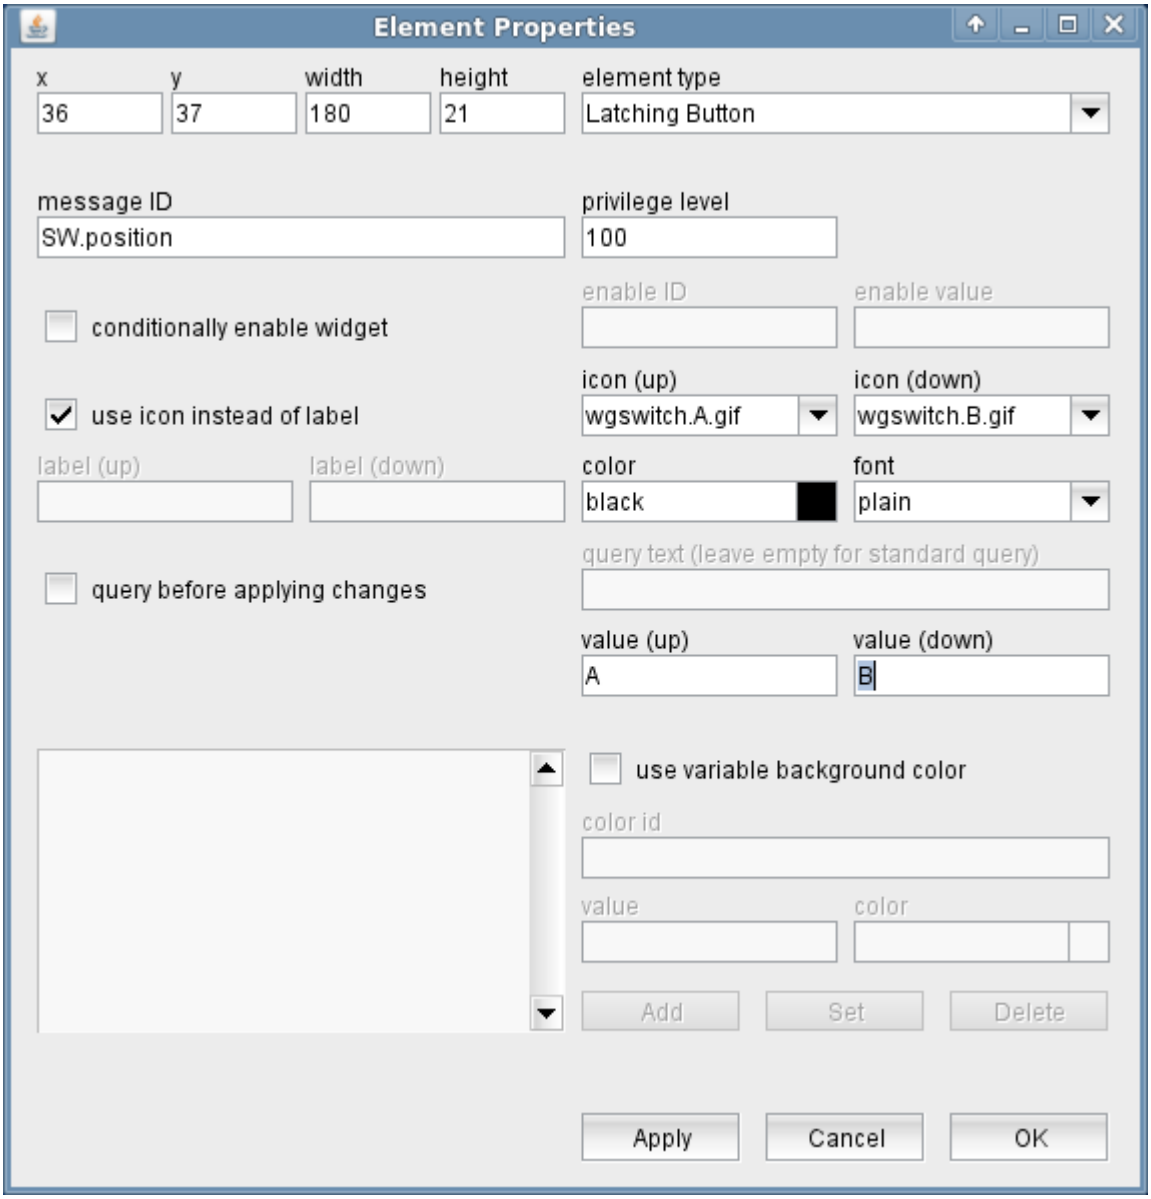
Each device in the sat-nms software knows two hidden variables which control storing and applying of device presets. The variables are called 'loadPreset' and 'savePreset'. Sending a string value to one of these variables will load or save a device preset with the name given as the variable value. Please note, that this feature uses preset files stored on the M&C/VLC itself. Hence, in a NMS environment these presets are only available for the particular VLC and these presets cannot be managed by the standard preset load/save functions in the device window toolbar in this case.

3.16.2.4.15 Latching Button

The *Latching Button* display element works much like the Parameter Button element described in the previous chapter, but specialized to show and control an enumeration parameter which knows exactly two states (e.g. on/off or true/false).

When the operator changes the state of the button by clicking it once, the latching button sends the 'other' parameter value to the device. On the other hand, if some other instance in the system changes the parameter state, the latching button recognizes this and changes the up/down state of the button accordingly.

Like the parameter button, the latching button may be labeled with text or an image. To reflect the actual state, the latching button always is configred with two text string or two image names which are shown according to the actual parameter value.



The attributes listed below may be configured to customize a display element of this type:

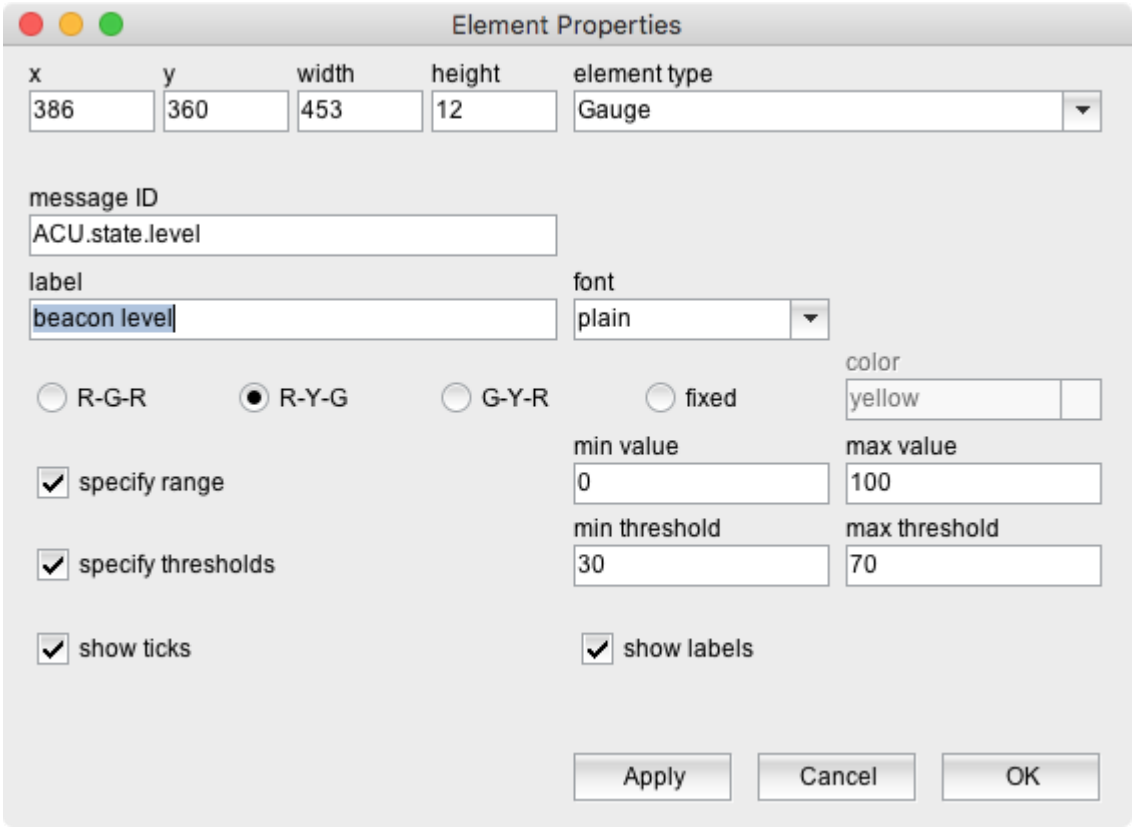
- message ID --- The message ID addresses the parameter the button shall control. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the ' Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- privilege level --- The privilege level necessary to access this button. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- Parameter buttons may be locked to disabled state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.

- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the button.
- use icon instead or label --- Check this mark in order to make the button show an icon instead of a label text.
- icon (up) --- The name of the icon to be shown in "up" state of the button. The field provides a list of all available icons / images on the sat-nms server.
- icon (down) --- The name of the icon to be shown in "down" state of the button. The field provides a list of all available icons / images on the sat-nms server.
- label (up) --- This label text is drawn on the button in "up" state.
- label (down) --- This label text is drawn on the button in "down" state.
- color --- The color attribute of a parameter element sets the color of the label shown on the button. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font to be used for the button label.
- query before applying changes --- Check this mark to make the element show a query before a parameter gets actually commanded.
- query text --- The query text to be shown in the pop-up window. you may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set.
- value (up) --- The value to be sent when the button is clicked an changes to "up" state.
- value (down) --- The value to be sent when the button is clicked an changes to "down" state.
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
    - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
    - To change the color assigned to a given parameter value, first select the table entry

of interest, change the color value and finally click "Set".
- To delete a value / color pair from the list, select the table entry and then click "Delete".

3.16.2.4.16 Gauge (Bar Graph)

The *Gauge* display element shows a numeric parameter value as a horizontal bar in an entry field like frame. The gauge element is capable to adjust the scale factor for the gauge automatically from the parameter's range definition. Alternatively the scale parameters may set explicitly.



The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses the parameter the element shall display. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the 'Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- label --- The label text drawn above the gauge / bar graph.
- font --- The font attribute applies to the label text shown above the gauge element.
- color scheme --- The gauge element knows three color schemes, allowing to change the bar color dynamically with the monitored value: | *color scheme* | *description* | | ---- | ---- | | R-G-R | RED/GREEN/RED The bar is displayed green while the value is between the minimum and maximum thresholds. If the value is outside the limits, the bar is displayed red. | | R-Y-G | RED/YELLOW/GREEN The bar is displayed red while the value is below the

minimum threshold value. It changes to yellow if the value is between the minimum and maximum thresholds. If the value exceeds the maximum threshold, the bar color changes to green. | | G-Y-R | GREEN/YELLOW/RED The bar is displayed green while the value is below the minimum threshold value. It changes to yellow if the value is between the minimum and maximum thresholds. If the value exceeds the maximum threshold, the bar color changes to red. | | fixed color | The bar is displayed with the color defined with the field 'color'. |

Please note, unless you specify min/max thresholds for the monitored value, only the fixed color mode is available.

- color --- The bar color used with the fixed color scheme. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- specify range --- Check this mark to define the range which is displayed by the gauge element.
- min value --- The minimum value of the displayed range.
- max value --- The maximum value of the displayed range.
- specify thresholds --- Check this mark to define the threshold values which are used for RGR and GYR color schemes.
- min threshold --- The minimum threshold value.
- max value --- The maximum threshold value.
- show ticks --- check this mark to make the element show scale ticks vor the min/max and threshold values below the gauge.
- show labels --- With this mark checked, below the gauge element labeled ticks are shown for the min/max and threshold values. (requires "show ticks"). Bar graph elements with this option enabled should be configured with a width that is sufficient to show the scale labels without overlap.

Scaling and Threshold Display

Principally there are three ways to use a gauge element and to control the scaling of the display:

1. The default behavior of the gauge element is to examine the display scaling from the range definition of the displayed variable. The scaling is set that the complete range of the variable is displayed. This works fine if the displayed variable comes with a properly set range definition. Some drivers however define the range of read only parameters as 0..0 (means 'don't know the limits') or as a extraneous wide range to avoid overflows. Variables with such range definitions will not display in a meaningful way. The default scaling does not provide any threshold monitoring or tick display.
2. You may explicitly specify the display range with a range definition in the appropriate fields as described above. Such a definition overwrites the default scaling of the gauge element. You may include unit descriptions to the scale values, but you should consider, that long scale labels tend to overlap and become unreadable.
3. If you let the gauge element monitor the 'gauge' status variable of aLevel-Set logical device, this state variable will provide it's own display range and threshold definition. This

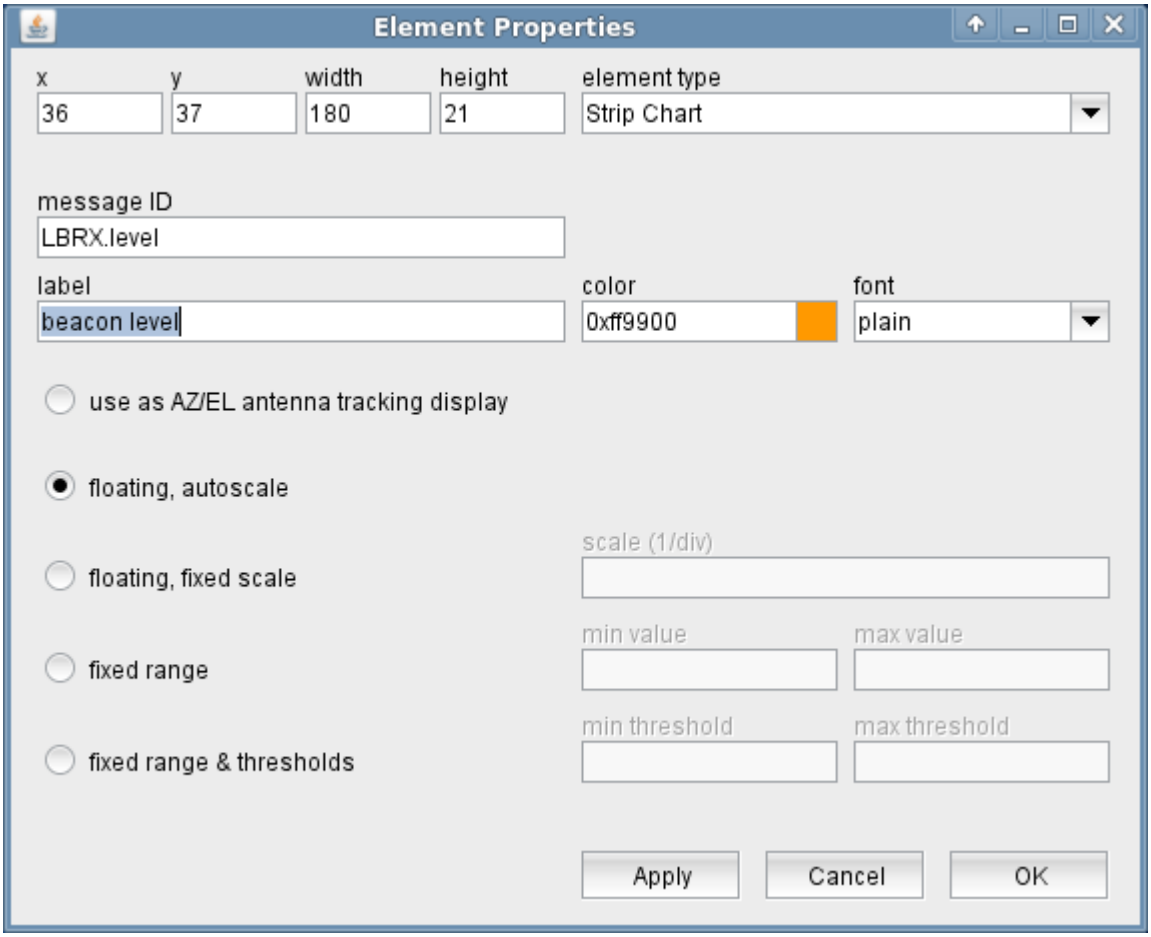
replaces the default scaling and also a scaling explicitly defined for this element. The display range provided by the Level-Set device always includes threshold definitions, but does not turn on the display of labeled ticks under the bar graph. If you want to enable this, you have to specify a dummy display range and thresholds in the fields described above.

3.16.2.4.17 Strip Chart

The *Strip Chart* display element shows a strip chart of a numeric parameter. The chart advances with a constant speed of 1 pixel / second. The default y-scale is 1/division but may be changed by clicking to the chart with the right mouse button.

By default, the strip chart element lets the y-scale offset follow the displayed value that the recent measurement samples are shown in the diagram. This behavior is optimized for applications where the strip chart shall indicate a 'trend' for the displayed value, using an element height of only 50 pixels or less.

Optionally you may disable this variable scaling by defining fixed scale values in the 'Text / Image Name' field. With this fixed y-axis scaling an additional threshold check may be added, turning the chart background to red if the actual value exceeds the defined limits. When used with limit checking, the height of the chart should be at least 100 pixels.



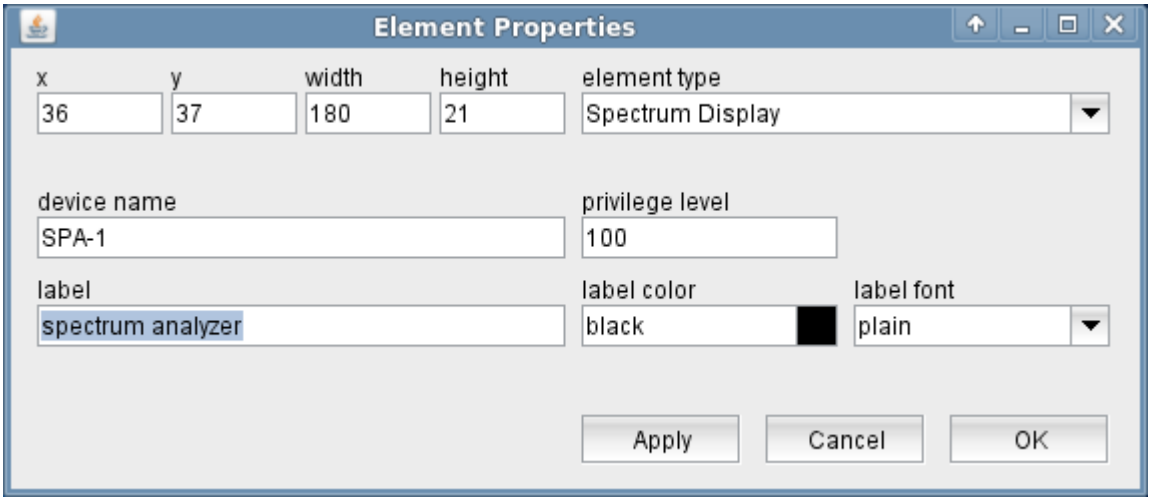
The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses the parameter the element shall display. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the 'Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- label --- The label text drawn above the strip chart
- color --- Defines the pen color and the color of the label drawn above the chart. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font attribute applies to the label text shown above the strip chart.
- display mode --- Selects the display mode of the strip chart element. Five modes are available:**use as AZ/EL antenna tracking display** The strip chart display element also may be used to place an Az/El diagram into a user interface for an Antenna-Tracking logical device. To do this, select this option and let the display element listen to the '.state.mode4' parameter of the Antenna-Tracking device. The Az/El diagram has a fixed size, you should align the display element size that the diagram is displayed properly.**floating, autoscale** This is the standard display mode. The strip chart aligns the reference value (the medium display line) in a way that every new display point is shown on this line. The initial scale is 1 unit/div.**floating, fixed scale** Works like the above mode, but the scale value gets initialized with a user defined value.**fixed range** The min/max values to display are defined explicitly, there is no automatic reference level alignment with this mode.**fixed range & thresholds** Like the above mode, but additionally there are min/max thresholds defined. If the actual value of the monitored parameter, the display background changes to red.
- scale --- The initial scale value used with the 'floating, fixed scale' mode.
- min value --- The minimum value to display for the fixed range display modes.
- max value --- The maximum value to display for the fixed range display modes.
- min threshold --- The lower threshold value for the "fixed range & thresholds" mode.
- max threshold --- The upper threshold value for the "fixed range & thresholds" mode.

3.16.2.4.18 Spectrum Display

The *Spectrum Display* element embeds the spectrum display of a spectrum analyzer device in the screen. The display may be scaled to an almost arbitrary size, however the following limitations apply:

- The annotation labels which reflect the actual spectrum analyzer settings are not scaled with the display element. If the element is very small, the labels may overlap and become unreadable.
- Resizing the spectrum display element is only possible in certain steps, the grid behind the spectrum curve is always made up of *10*n + 11* pixels in one dimension. The screen editor software knows about this, snaps the size of the element to the next (smaller) valid size after you release the mouse button.



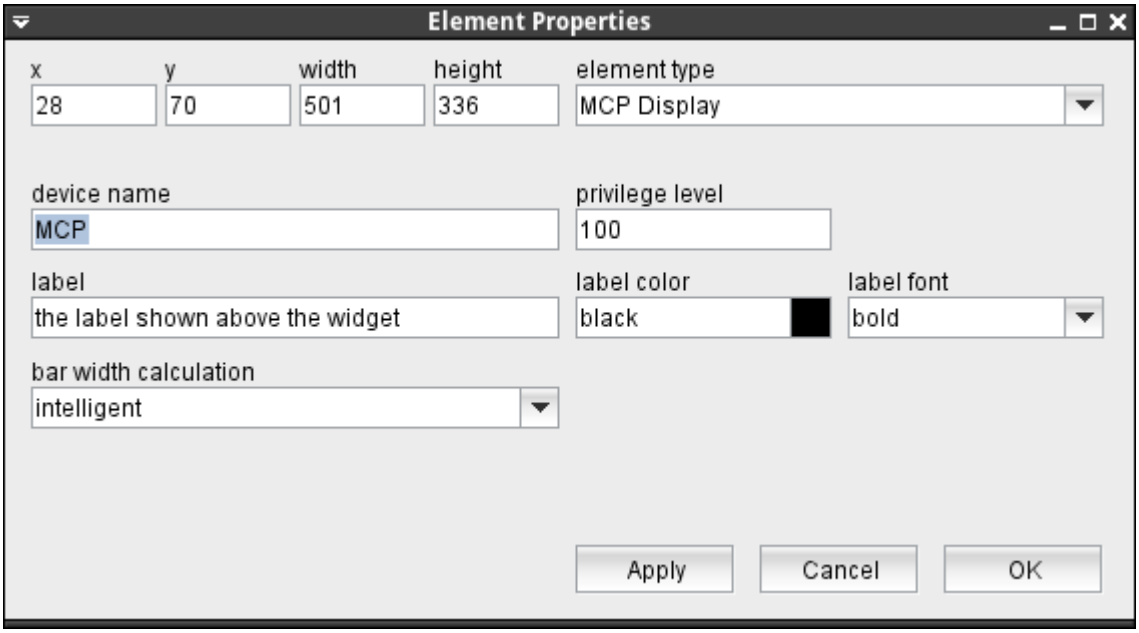
The attributes listed below may be configured to customize a display element of this type:

- device name --- The name of the spectrum analyzer device to operate.
- privilege level --- The privilege level necessary to operate the spectrum analyzer device.
- label --- The annotation label displayed above the spectrum display.
- label color --- The color of the label displayed above the spectrum display. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- label font --- The font attribute sets the font of the label shown above the element.

3.16.2.4.19 MCP Display

The *MCP Display* element embeds the measurement display of a spectrum analyzer device in multi channel power measurement mode into the screen. The display may be scaled to an almost arbitrary size, however the following limitations apply:

- The annotation labels which reflect the actual device settings are not scaled with the display element. If the element is very small, the labels may overlap and become unreadable.
- Channels may displayed very narrow if the display is too small, labels may become unreadable in this case.

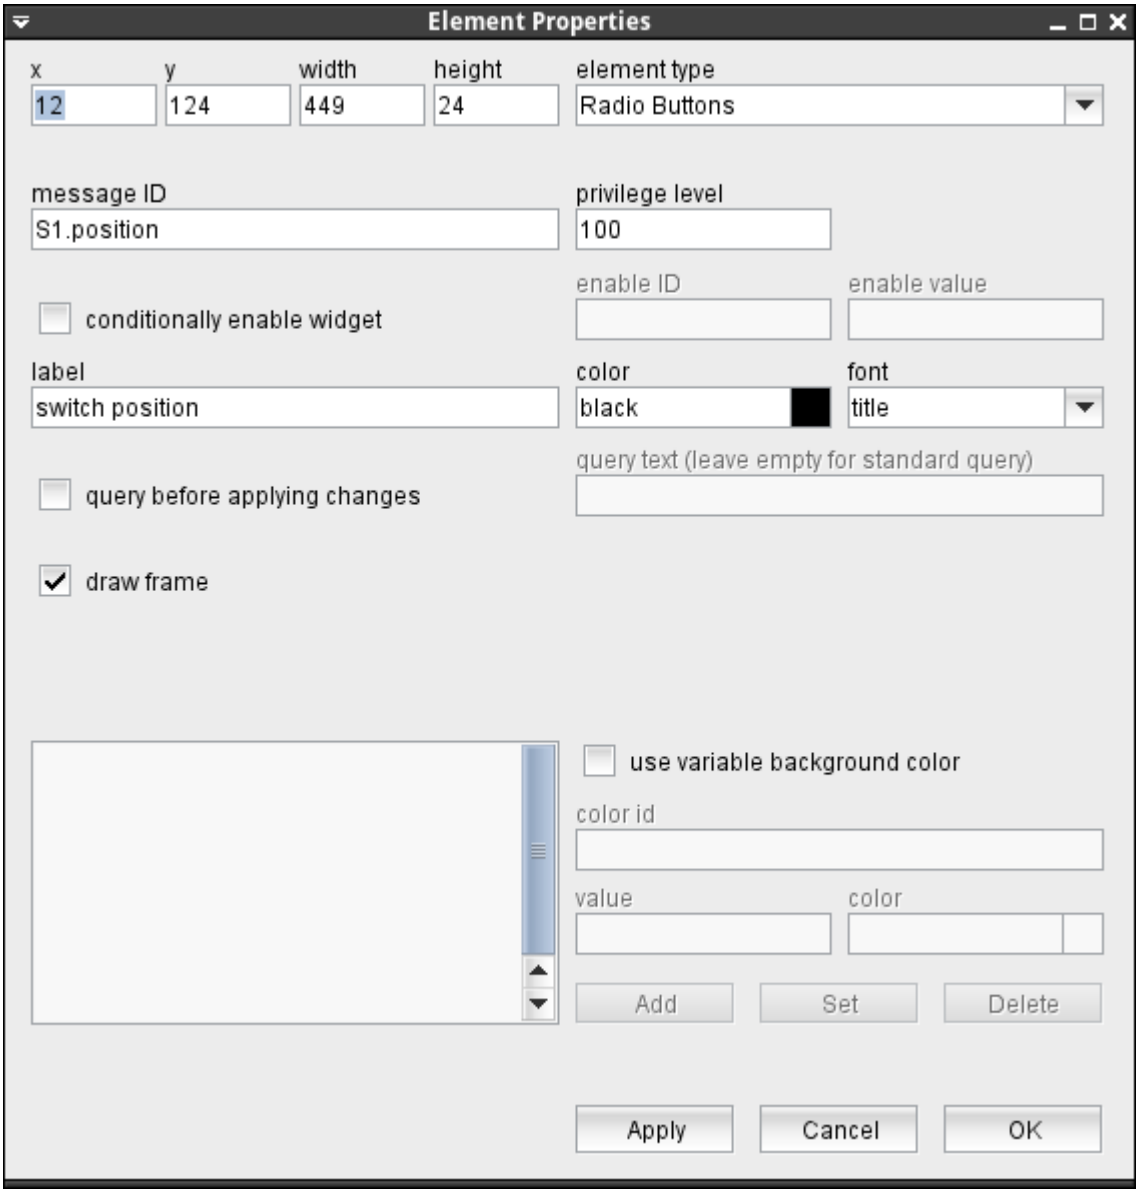


The attributes listed below may be configured to customize a display element of this type:

- device name --- The name of the spectrum analyzer device to operate.
- privilege level --- The privilege level necessary to operate the spectrum analyzer device.
- label --- The annotation label displayed above the spectrum display.
- label color --- The color of the label displayed above the spectrum display. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- label font --- The font attribute sets the font of the label shown above the element. This font also applies to the name labels shown below the channel bars.
- bar width calculation --- This parameter lets you select how the screen element calculates the width of the bars from the channels' bandwidth. 'all same width' draws all bars with the same width, regardless of the channels' bandwidth. 'strict proportional' calculates the width of the bars following the ratio of bandwidths - even if this leads to very narrow bars with unreadable figures. 'intelligent' which is the default, draws wide channels wider than narrow ones, but limits the ratio of bar widths to 1:3.

3.16.2.4.20 Radio Buttons

The *Radio Buttons* display element is a component to display and edit CHOICE type M&C parameters as a number of radio buttons. Depending on the height of the element, radio buttons are positioned in a row or in a column. In the screen editor, the parameter element is shown as a simple rectangle rectangle.



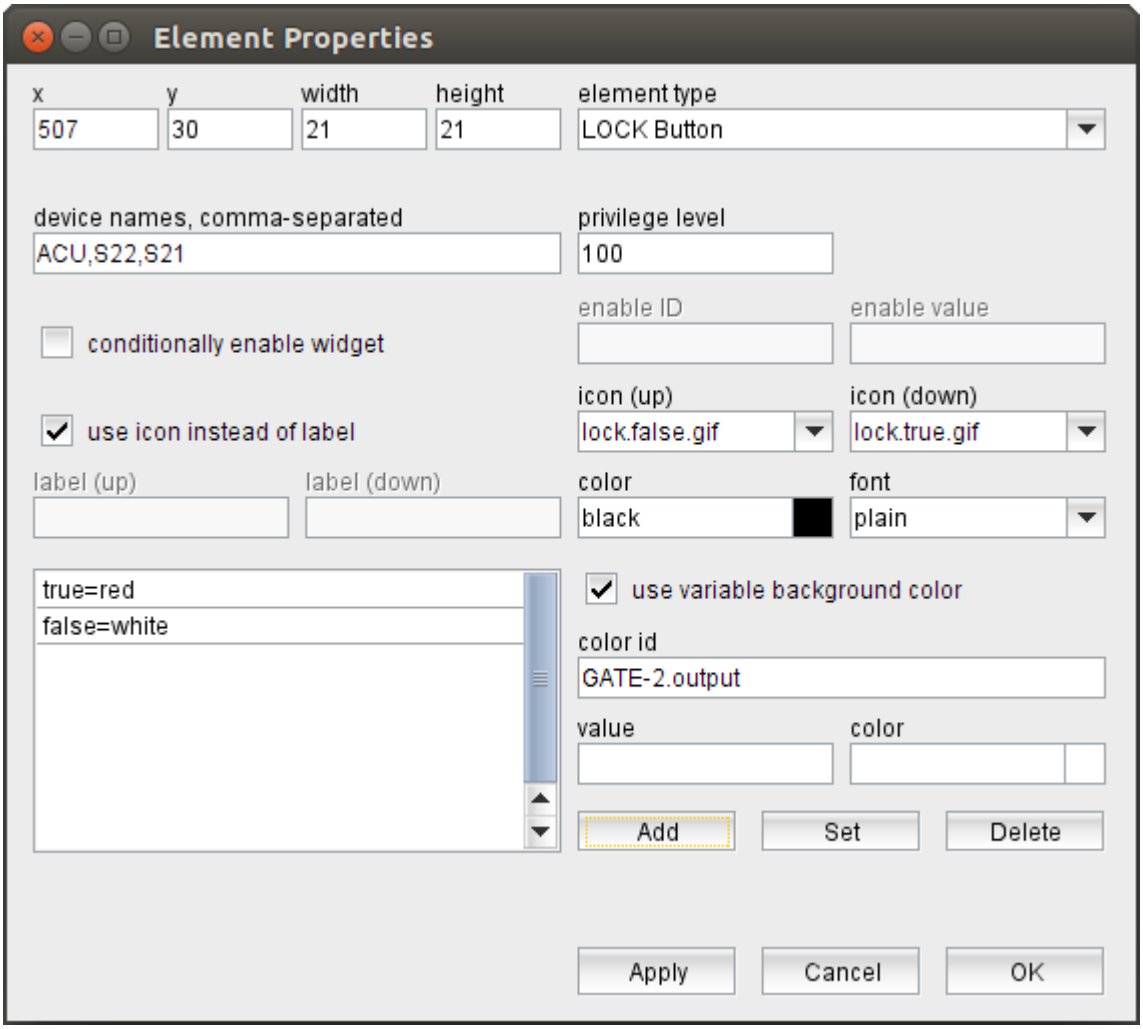
The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID addresses the parameter the element shall display or edit. The message ID consists of the device name followed by a colon and the name of the parameter. *XMIT-1.tx.on* for example addresses the variable *tx.on* at a device named *XMIT-1* . With the ' Device Driver Index ' in the appendix of this document there is a list of variable names provided for each device driver the software supports.
- privilege level --- The privilege level necessary to change this parameter. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- Parameter fields may be locked to read only state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.

- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the entry field.
- label --- The label text is drawn above the element.
- color --- The color attribute of a parameter element sets the color of the label shown above the entry field. The text in the parameter field itself always is shown in the default text color of the selected look & feel. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font attribute applies to the text shown in the parameter field itself. The label text is shown with the standard ("plain") font size for all font selections except the smallest one. In the latter case the label is drawn using this small font size, too.
- query before applying changes --- Check this mark to make the element show a query before a parameter gets actually commanded.
- query text --- The query text to be shown in the pop-up window. you may leave this field empty, the program uses a standard query text in this case.In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set.
- draw frame --- Checking this mark makes the element show a rectangular frame around the radio buttons.
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
  - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
  - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
  - To delete a value / color pair from the list, select the table entry and then click "Delete".

3.16.2.4.21 LOCK Button

The LOCK Button lets you lock the operation of a number of device devices that no other user can change device settings. The button is in pressed state if at least one of the devices it is assigned to is locked by some user. You only may realease the button if you set the lock by yourself of if you have a privilege level of 150 or more.



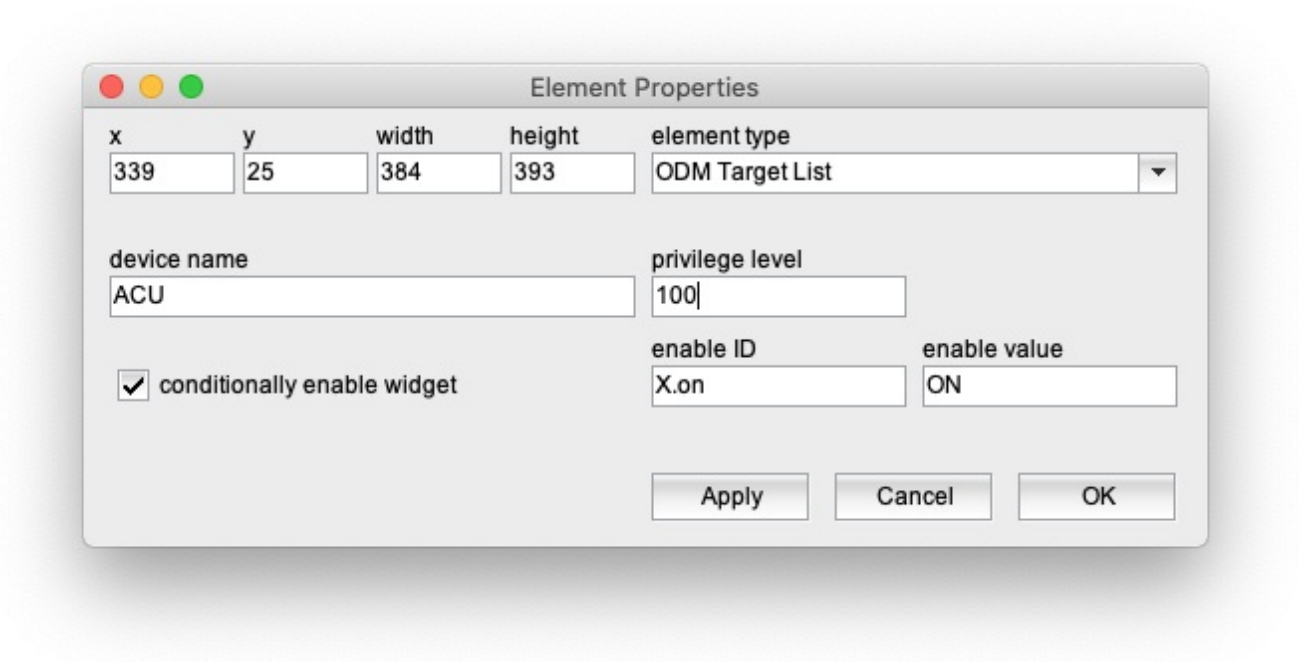
The attributes listed below may be configured to customize a display element of this type:

- device names, comma-separated --- As the field heading suggests, this field expects a comma-separated list of the devices, this button shall control.
- privilege level --- The privilege level necessary to access this button. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- Parameter buttons may be locked to disabled state unless another parameter matches a given value. For instance, changing the position of a wave guide switch may be inhibited while the carrier is switched on. Check this mark to activate this feature.
- enable ID --- This field defines the ID for the enabling parameter.
- value --- The value belonging to the parameter above. The actual value of the parameter

addressed by "enable ID" mut match this value in order to enable the button.
- use icon instead or label --- Check this mark in order to make the button show an icon instead of a label text.
- icon (up) --- The name of the icon to be shown in "up" (unlocked) state of the button. The field provides a list of all available icons / images on the sat-nms server.
- icon (down) --- The name of the icon to be shown in "down" (locked) state of the button. The field provides a list of all available icons / images on the sat-nms server.
- label (up) --- This label text is drawn on the button in "up" (unlocked) state.
- label (down) --- This label text is drawn on the button in "down" (locked) state.
- color --- The color attribute of a parameter element sets the color of the label shown on the button. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation. '#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.
- font --- The font to be used for the button label.
- use variable background color --- Checking this mark enables the variable background color feature for this screen element. Depending on the actual value of the variable addressed by 'color id', the element's background is set using the translation table shown in the lower left corner of the dialog. If the actual value of the color id variable does not match any of the table entries or if no color id is specified, the first color in the list is used to draw the element's background.The buttons Add/Set/Delete along with the value and color fields are used to edit the color translation table.
- color id --- The message ID of the parameter which controls the background color of this element.
- value --- The parameter value of the actually selected table entry
- color --- The color specification of the actually selected table entry. This may either be the name of a basic color (red, yellow etc.) or a hexadecimal RGB color specification like '#FF8000'. The latter defines some sort of orange, consisting of 0xFF red, 0x80 green and 0x00 blue. The actually selected color is shown in the right part of the entry field, clicking to this opens a color chooser dialog which lets you select / compose the the color to your needs.
- Add / Set / Delete --- These buttons control editing the color translation list.
    - To add a new value / color pair to the list, fill the value and color fields, then click to "Add".
    - To change the color assigned to a given parameter value, first select the table entry of interest, change the color value and finally click "Set".
    - To delete a value / color pair from the list, select the table entry and then click "Delete".

3.16.2.4.22 ODM Target List

The ODM Target List screen element lets you embed the list of targets of aSatService-ACU-ODM antenna controller in the screen. Targets may be recalled (which moves the antenna to the stored position and sets the tracking parameters associated with this target), saved or deleted.



The attributes listed below may be configured to customize a display element of this type:

- device name --- This parameter is interpreted differently depending on the context where the ODM Target List screen element resides:
  - When placed in a user defined screen or in the main screen of the application, 'device name' must be set to the name of the ODM device it shall refer to.
  - When placed in the device screen of another device which defines a configuration variable with the antenna controller device name, the name of this configuration variable must be entered as the 'device name'.
  - Finally, when used in the device screen of the ODM device itself, 'device name' must de set to '@'

Please note, that the ODM Target List screen element only works withSatService-ACU-ODM antenna controller device type, other antenna controllers are not supported.

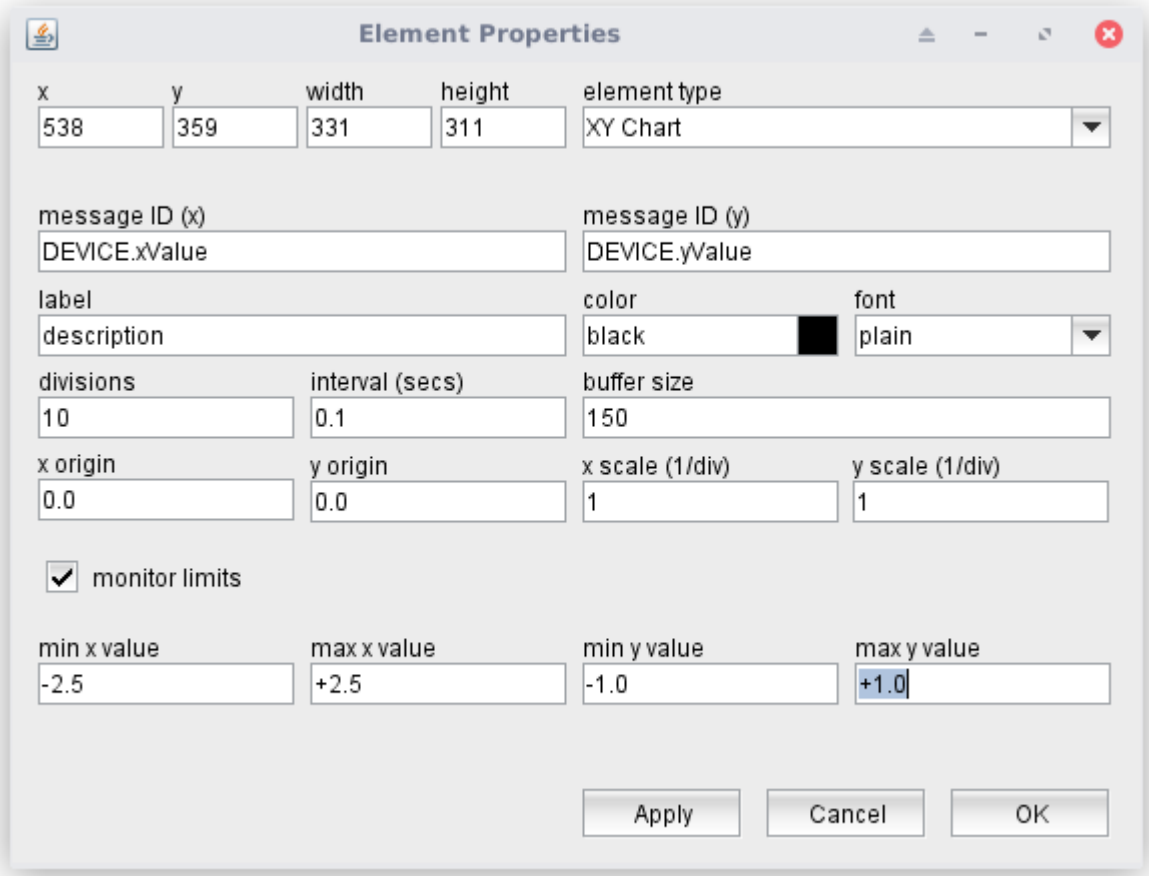
- privilege level --- The privilege level necessary to access this element. The predefined screens of the software use 100. In your own screens you may set certain parameters to higher privilege levels, limiting the group of operators permitted to change the parameter.
- conditionally enable widget --- The target list widget may be locked to disabled state unless another parameter matches a given value. For instance, a TX-ON state may disable the selection of another satellite by means of the target list widget.
- enable ID --- This field defines the ID for the enabling parameter. When used in a device screen, the ID is interpreted as a variable name of the device, this screen belongs to.
- value --- The value belonging to the parameter above. The actual value of the parameter addressed by "enable ID" mut match this value in order to enable the button.

3.16.2.4.23 XY Chart

This element shows the relation of two numeric variables in an X/Y diagram, featuring a 'track' which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.

The X/Y chart display may be scaled to an almost arbitrary size, however the following limitations apply:

- The annotation labels which reflect the actual display settings are not scaled with the display element. If the element is very small, the labels may overlap and become unreadable.
- Resizing the X/Y chart display element is only possible in certain steps, the grid behind the curve is always made up of a number pixels in one dimension which is divisible by the configured number of diagram divisions without remainder. The screen editor software knows about this, snaps the size of the element to the next (smaller) valid size after you release the mouse button.



The attributes listed below may be configured to customize a display element of this type:

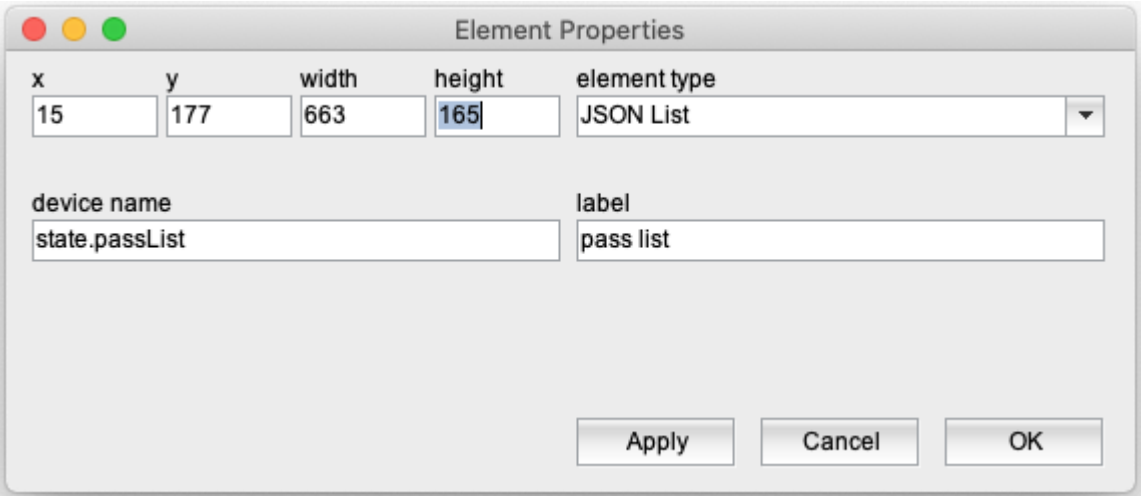
- messageID(x) message ID (y) --- The message IDs of the parameters to show.
- label --- The annotation label displayed above the X/Y chart
- color --- The color of the label displayed above the X/Y chart. Colors may be specified by standard color names like red / green / blue or using a hexadecimal RGB notation.

'#FFFF00' for example specifies yellow. You may click to the color example field in order to open a color chooser dialog and select the color from there.

- font --- The font attribute sets the font of the label shown above the element.
- divisions --- The number of divisions shown in the diagram for both directions. You may enter arbitrary values here, but to achieve some readability, you are encouraged to us common values like 2 ('hair cross'), 4 or 10.
- interval --- The update time interval for the display in seconds. 0.1 means to add every 100msec a new value to the display and remove the oldest value from the buffer at the same time.
- buffer size --- The display maintains a "first in first out" buffer of a size defined with this parameter. The buffer provides a short time memory the display shows as a trace of past values. Values in the range 100-300 are a good choice, larger values may slow down the client application. Please note, that the buffer gets cleared when the window is closed.
- x origin y origin --- The origin values refer to the*center* of the diagram. Using an even number of divisions helps to identify the diagram center as the crosspoint of the middle grid lines
- x scale y scale --- The scale values are per division. with xorigin = 0.0 and x scale = 1.0 an x value of 1.0 gets displayed one division right of the diagram center.
- monitor limits --- With this mark checked, the display monitors the*actual* X/Y values to be within the limits defined below. The limit values are shown as a dark red rectangle. When the while the actual X/Y values exceed the limits, the disgram background becomes red.
- min x value max x value min y value max y value --- The limit values for X and Y to be checked.

3.16.2.4.24 JSON List

The JSON List element is a special screen element required for some devices which distribute a state table/list in JSON format. It can only be used for this purpose.

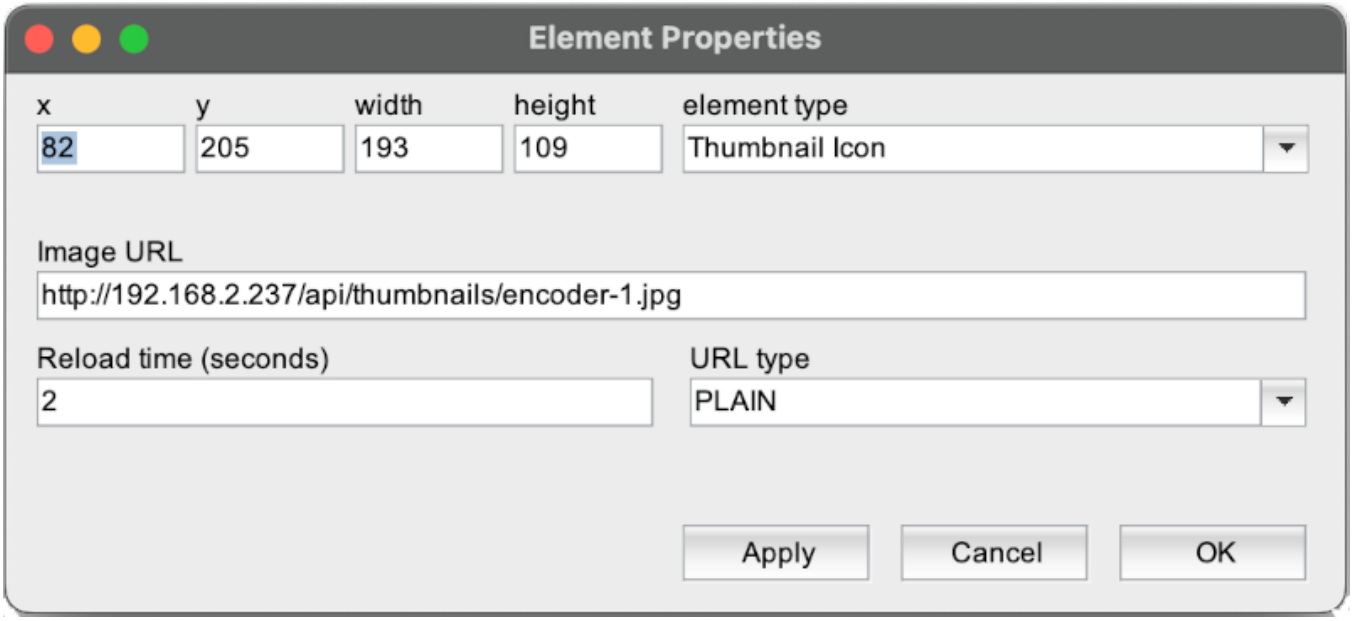


The attributes listed below may be configured to customize a display element of this type:

- message ID --- The message ID of the JSON list to show.
- label --- The annotation label displayed above the element

3.16.2.4.25 Thumbnail Icon

The Thumbnail Icon element lets you display a thumbnail of the video actually processed by a device lika an encoder, decoder or gateway. The displayed icon is a static image, updated every couple of seconds.



The attributes listed below may be configured to customize a display element of this type:

- Image URL --- The URL where to fetch the image.
- Reload Time --- The interval when the image shall be reloaded (seconds)
- URL Type --- One of PLAIN or ADVANCED. With PLAIN the URL is used as it is, with ADVANCED CGI parameters for the actual time and the image width and height are appended to the URL.

REMARKS

- The device to get the thumbnail images from must support this feature.
- The device to get the thumbnail images from must be accessible in the network from the client's point of view.
- Thumbnail Icons are - when resized by mouse drag in the GUI editor - forced to 16:9 ratio. If another image ratio is required, image width and height must be entered in the dialog shown above.
- in PLAIN mode, the image received from the device gets scaled to fit the screen element size, in ADVANCED mode no scaling is done as the software queries the image already in the correct size from the device.

3.16.2.5 Configuring a Tabbed View Client

Configuring a Tabbed View user interface is mainly a job of planning and organization. The layout of navigation bar buttons and VLC screens ist defined in a configuration file, but before editing this file some preparation have to be done:

1. Define, which views / tabs shall be present in the Tabbed View Client
2. For each tab define which VLC screens shall be contained. Edit the screens using the sat-nms Screen Editor Window .
3. Edit the Tabbed View configuration file to put things together.

The NMS directory tree provides an own subdirectory named "tviews", containing the configuration files for the Tabbed View Client. The file called "default" is used by the client, unless the client is forced to read another file (that's a command line option of the client program)

Configuration file format

The configuration file is a free form text file defining the tab layout with a couple of keywords. In the file, whitespace and C/C++ style comments are ignored. Syntax and keywords are best explained using this example:

```
// example tabbed view definition file
//

SHOW-FAULTICON NO
SUPPRESS-OFFLINE-FAULTS YES
SPACING 3

BUTTON "TAB 1"

   SCREEN vlc0001 vlc0001_rx_Tabscreen
   SCREEN vlc0002 vlc0002_rx_Tabscreen
   SCREEN vlc0003 vlc0003_rx_Tabscreen
   GROUP G1

GAP

BUTTON "TAB 2"

   SCREEN vlc0003 vlc0003_tx
   SCREEN vlc0002 vlc0002_tx
   SCREEN vlc0001 vlc0001_tx

DEFAULTS

   USER u1 "TAB 2"
```

The file starts with two global definitions:

- SHOW-FAULTICON --- Must be followed by YES or NO. Defines if the main toolbar shall include a system wide "new fault" indicator. Depending on the type of usage of the equipment managed by the NMS, the system wide fault indicator may be red all the time, irritating the operators. In this case you may want to suppress the indicator by specifying

"SHOW-FAULTICON NO". If you omit the SHOW-FAULTICON definition, the Tabbed View Client shows the fault indicator.
- SUPPRESS-OFFLINE-FAULTS --- Must be followed by YES or NO. Defines if faults of an off-line VLC are signalled with a red lamp in the Tabbed View's navigation bar:
  - With NO, an off-line VLC is shown with a red lamp if the VLC signalled a fault when it was on-line the last time.
  - With YES, of-line VLCs always are shown with s gray lamp.

Default is NO, without the SUPPRESS-OFFLINE-FAULTS definition the software shows off-line VLCs with a red lamp if there is a faul known for the VLC.

- SPACING --- Must be followed by a number in the range 1..100. The SPACING value defines the room in pixels, the program reserves above and below each button. Hence, the space between two buttons is two times this value. The default for SPACING is 10 pixels.

The sequence of these definitions doesn't matter, however they should appear before the first BUTTON definition.

The BUTTON keyword defines a button in the navigation bar. It must be followed by the button label, enclosed in double quotes. Buttons are identified by their label, hence button labels should be unique within a Tabbed View definition.

The BUTTON definition also starts the definition of the tab / view assigned to this button. Within the tab definition, the following definitions are expected:

- GROUP *group-name* --- The GROUP definition is optional and may appear only once. Specifying a group for a button restricts the access to this tab to users being part of the specified user group. Omitting the GROUP definition for a button lets all (loggen in) users access this tab.
- SCREEN *vlc-id screen-name* --- The SCREEN clause defines one VLC screen appearing in the tab. The keyword SCREEN must be followed by the ID of the VLC to connect to (using the notation vlc####) and the name of the screen definition to display. The screen definition file is expected in the 'screens' directory, the file name must not contain any whitespace.There may be multiple SCREEN definitions for one tab, the screens are layed out one below each other in the order they appear in the configuration file. The number of screens actually is not limited, but it makes no sense to define more screens than fitting into the fullscreen application window. There are no scrollbars provided to manage a virtual screen larger than the physical screen size.

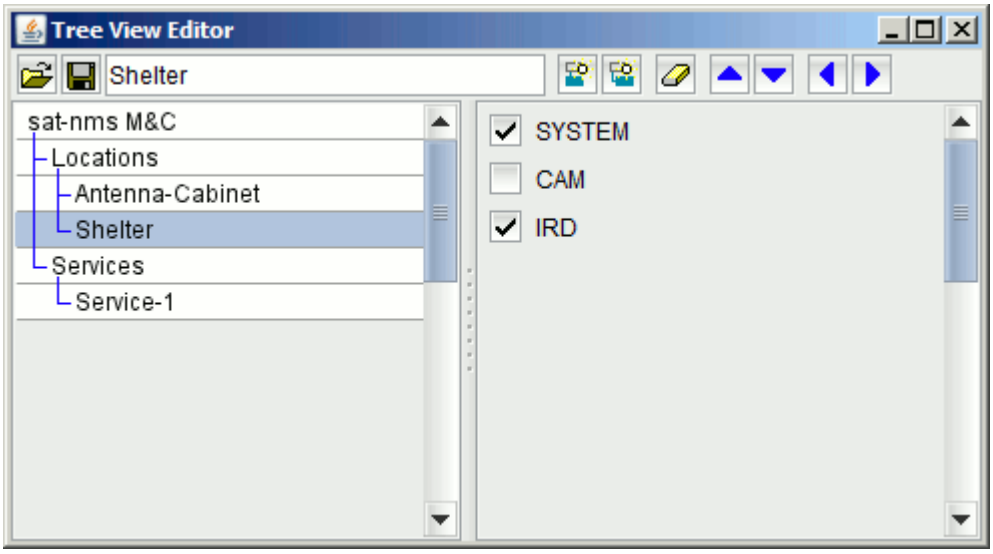
In the sequence of BUTTON definitions the keywords GAP and LINE may be used instead of a button clause. As GAP suggests, this tells the software to place a gap (10 pixels height) between two buttons in the navigation bar. LINE draws a horizontal line to separate buttons.

The BUTTON definitions optionally may be followed by a list of default screen assignments, preceded by the keyword DEFAULTS. Each default screen definition consists of the keyword USER, folled by a user name and the label of a button defined above. The button label must be enclosed in double quotes.

Defining a default tab for a certain user means to tell the software that this tab shall be opened automatically when the user logs on. For each user only one default tab may be defined. Together with the autologin feature available as command line option when the Tabbed View gets invoked, the program may configured to show one tab automatically when started.

3.16.2.6 Configuring the M&C Tree View

The Tree View Editor window lets you define or modify the tree / subsystem hierarchy used by the M&C Tree View. You open the Tree View Editor by clicking the appropriate tool bar button of the Tree View.



The left part of window shows the subsystem tree structure, the right part a list of all devices configured in the M&C system. Editing / modifying the tree structure is straight forward:

Selecting a tree node with the mouse shows the name of this node in the text field in the tool bar and at the right side places a checkmark in front of all devices which are attached to this node. Checking / unchecking devices attaches or detaches the to/from the actual tree node. Using the toolbar buttons you may add or remove tree nodes and move them up or down:

- --- Re-load the tree definition from its disc file, thus reverting all changes to the last saved state.
- --- Stores the changes made at the tree at the server and updates all Tree View windows actually open.
- --- Shows the name of the selected node. The name may be changed by editing the field and pressing RETURN. Please note, that changing a node's name will re-reference the node from its user screen and also will change the message IDs of the subsystem fault message of this node ans all its children.
- --- Adds a new node to the tree. The new node will be added as the last sibling of the selected node.
- --- Adds a new node to the tree. The new node will be added as the last child of the selected node.

- --- Removes the selected not an all its children from the tree.
- --- Moves the selected node one position up in the list of its siblings. Does nothing if the note is already at the topmost position.
- --- Moves the selected node one position down in the list of its siblings. Does nothing if the note is already at the lowest position.
- --- Moves the selected note on level up in the tree hierarchy. The highest level a node may be of is one below the root node.
- --- Moves the selected node one level down in the tree hierarchy. The node must have at least one sibling for this.

The nodes of the tree view in the sat-nms software also can be seen as subsystems of the M&C. The M&C server creates a fault flag for wach tree view node / subsystem which is defined using the Tree View Editor.

Subsystem fault flags summarize the fault states of all devices and subsequent tree nodes which are children the particular node. Like the summary fault of a device, the subsystem fault is one of "OK.", "WARNING" of "Summary FAULT". It states the most severe fault state one of the summarized devices or subsystems reports.

The subsystem fault flags can be accessed for display at the GUI through their parameter ID, which is defined as "SUBSYSTEM. ... .fault", where the three dots are to be replaced by the fully qualified name of the tree node. If for example a tree node "/Locations/Shelter-B" exists, the fault ID for this node is "SUBSYSTEM.Locations.Shelter-B.fault".

4 Administration

This section of the manual gives some information how to administer and configure the various components of the satnms M&C software. It describes how to invoke the programs used by the software and which command line parameters these programs understand.

Chapter Configuration Files contains a reference to all configuration parameters which can be defined in varipus configuration files of the software.

Chapter Event Database Configuration and Event Notification Add-Ons describes how to configure the event database and opetional add-ons which may be configured to trigger some actions on certain events.

Finally, the chapter Remote Control describes the features built into the satnms M&C software for being remotely monitored and controlled by an external software.

4.1 Program Invocation

The satnms M&C software consists of a number of programs running independently on the same or on separate machines. The following chapters describes how to invoke these programs and which command line parameters they accept.

4.1.1 M&C Server

The M&C server is run as a system service and is automatically started when the operating system comes up. Normally there is no need to change the command line parameters which are passed to the program by the the startup scripts. Most parameters of the M&C server may be configured by editing the vlc.propertis configuration file.

If the M&C server must be stopped or started explicitly, the follwing commands sould be used:

```
$ systemctl stop satnms
```

and

```
$ systemctl start satnms
```

respectively. To start or stop the M&C one must be logged in as 'root' on the machine hosting the M&C server.

4.1.2 Backend Server

The backend server is run as a system service and is automatically started when the operating system comes up. There are no command line parameters for the server program itself, the behavior of the backend is entirely controlled by the backend.properties file.

If the backend server must be stopped or started explicitly, the follwing commands sould be

used:

```
$ systemctl stop backend
```

and

```
$ systemctl start backend
```

respectively. To start or stop the backend one must be logged in as 'root' on the machine hosting the backend server.

4.1.3 Client Programs

The following paragraphs list the command line invocation syntax and options for the sat-nms client software. Being pure Java applications, the sat-nms clients may be run on severals operating systems. The explanations given in the following are mostly independent from the operating system you are using. For all examples given below, we assume that the file "client.jar" is located in your current working directory.

M&C Client

The M&C client program is invoked by a command line looking like this:

java -cp client.jar satnms3.gui.MCFrame [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -m x0,y0,x1,x2,xc,yc --- Specifies the (overall) bounds of a multi monitor setup. When operated on a single monitor PC, the client automatically determines the screen size and ensures that automatically placed windows remain within the bounds of the screen. The -m option is not necessary in this case. With multiple monitors, the abolute bounds of the rectangle enclosing all monitors must be specified with the -m option. -m must be followed by a space character and 6 numbers separated by comma characters: x0 = x coordinate of the top left corner y0 = y coordinate of the top left corner x1 = x coordinate of the bottom right corner y1 = y coordinate of the bottom right corner xc = x coordinate of center position yc = y coordinate of center position Example: 0,0,3840,1080,2880,540 describes a layout with two full HD monitors located side by side. The center position is defined as the center of the right monitor (the splash screen and some other windows are

shown centered at this point.

- -f 0 -f 1 --- Starts the client in full screen mode. The main window covers the complete screen, no window decorations are shown. *-f 1* shows the satnms toolbar (to launch the event log for example) *-f 0* suppresses the tool bar.The full screen mode is intended to be used with touch screen panels. There are limited capabilities to handle child windows in *-f 0* mode, depending on the operating system of the client pc.
- -t --- Starts the client without the toolbar.
- -n 1 -n 2 -n 3 --- Tells the client how to treat "new faults". Without the -n option, new faults are not reported separately. The fault indicator in the main window's toolbar ia active while the server's summary fault is active.
    - **n1** --- The program treats new faults separately. A fault is new until an operator acknowledges it by clicking into the fault indicator or by acknowledging the fault in the event log or event report window. The new fault is displayed as a red mark labeled "NEW FAULT". If the fault disappears without being acknowledged, a gray "NEW FAULT" mark is shown.
    - **n2** --- Behaves like **-n 1** , but makes the program ring the keyboard bell while a new fault is pending.
    - **n3** --- Works like the previous, but suppresses the very first "NEW FAULT" after the start of the client. New faults which occurred while the client program did not run are not signalled, nor are gray "NEW FAULT" conditions. Only new faults recognized while the client program runs are shown.
- -s <screen-name> --- Tells the program to load the given screen definition file instead of the "default" screen on startup. Screen definition files are expected in the "screens" subdirectory of the server. The -s also suppresses the display of the applications's splash screen on startup.
- -v --- Suppresses the program version match check on startup
- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.
- -y <layout-name> --- Tells the program to load the given window layout instead of the layour "default".

TreeView Client

The TreeView version of the M&C client program is invoked by a command line looking like this:

java -cp client.jar satnms3.gui.TreeView [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -m x0,y0,x1,x2,xc,yc --- Specifies the (overall) bounds of a multi monitor setup. When operated on a single monitor PC, the client automatically determines the screen size and ensures that automatically placed windows remain within the bounds of the screen. The -m option is not necessary in this case. With multiple monitors, the abolute bounds of the rectangle enclosing all monitors must be specified with the -m option. -m must be followed by a space character and 6 numbers separated by comma characters: x0 = x coordinate of the top left corner y0 = y coordinate of the top left corner x1 = x coordinate of the bottom right corner y1 = y coordinate of the bottom right corner xc = x coordinate of center position yc = y coordinate of center position Example: 0,0,3840,1080,2880,540 describes a layout with two full HD monitors located side by side. The center position is defined as the center of the right monitor (the splash screen and some other windows are shown centered at this point.
- -f 0 -f 1 --- Starts the client in full screen mode. The main window covers the complete screen, no window decorations are shown. *-f 1* shows the sat-nms toolbar (to launch the event log for example) *-f 0* suppresses the tool bar. The full screen mode is intended to be used with touch screen panels. There are limited capabilities to handle child windows in *-f 0* mode, depending on the operating system of the client pc.
- -t --- Starts the client without the toolbar.
- -o --- Enables automatic pop ups of the fault list window with every new fault.
- -n 1 -n 2 -n 3 --- Tells the client how to treat "new faults". Without the -n option, new faults are not reported separately. The fault indicator in the main window's toolbar ia active while the server's summary fault is active.
    - **n1** --- The program treats new faults separately. A fault is new until an operator acknowledges it by clicking into the fault indicator or by acknowledging the fault in the event log or event report window. The new fault is displayed as a red mark labeled "NEW FAULT". If the fault disappears without being acknowledged, a gray "NEW FAULT" mark is shown.
    - **n2** --- Behaves like **-n 1** , but makes the program ring the keyboard bell while a new fault is pending.
    - **n3** --- Works like the previous, but suppresses the very first "NEW FAULT" after the start of the client. New faults which occurred while the client program did not run

are not signalled, nor are gray "NEW FAULT" conditions. Only new faults recognized while the client program runs are shown.

- -s <screen-name> --- Tells the program to load the given screen definition file instead of the "default" screen on startup. Screen definition files are expected in the "screens" subdirectory of the server. The -s also suppresses the display of the applications's splash screen on startup.
- -v --- Suppresses the program version match check on startup
- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.

Tabbed View Client

The Tabbed View NMS client program is invoked by a command line looking like this:

java -cp client.jar satnms3.gui.TabbedView [options ...] <IP address of the server>

The IP address of the NMS server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -m x0,y0,x1,x2,xc,yc --- Specifies the (overall) bounds of a multi monitor setup. When operated on a single monitor PC, the client automatically determines the screen size and ensures that automatically placed windows remain within the bounds of the screen. The -m option is not necessary in this case. With multiple monitors, the abolute bounds of the rectangle enclosing all monitors must be specified with the -m option. -m must be followed by a space character and 6 numbers separated by comma characters: x0 = x coordinate of the top left corner y0 = y coordinate of the top left corner x1 = x coordinate of the bottom right corner y1 = y coordinate of the bottom right corner xc = x coordinate of center position yc = y coordinate of center position Example: 0,0,3840,1080,2880,540 describes a layout with two full HD monitors located side by side. The center position is defined as the center of the right monitor (the splash screen and some other windows are shown centered at this point.
- -s --- Suppresses the beeper ("silent").
- -t <tab-definition> --- Tells the program to load the given tab definition file instead of the "default" definition on startup. Tab definition files are expected in the "tviews" subdirectory of the NMS server.

- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -v --- Suppresses the program version match check on startup
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.

Service Client

The ServiceClient client program is invoked by a command line looking like this:

java -cp client.jar satnms3.sclient.ServiceClient [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -n 1 -n 2 -n 3 --- Tells the client how to treat "new faults". Without the -n option, new faults are not reported separately. The fault indicator in the main window's toolbar ia active while the server's summary fault is active.
    - **n1** --- The program treats new faults separately. A fault is new until an operator acknowledges it by clicking into the fault indicator or by acknowledging the fault in the event log or event report window. The new fault is displayed as a red mark labeled "NEW FAULT". If the fault disappears without being acknowledged, a gray "NEW FAULT" mark is shown.
    - **n2** --- Behaves like **-n 1** , but makes the program ring the keyboard bell while a new fault is pending.
    - **n3** --- Works like the previous, but suppresses the very first "NEW FAULT" after the start of the client. New faults which occurred while the client program did not run are not signalled, nor are gray "NEW FAULT" conditions. Only new faults recognized while the client program runs are shown.
- -s <service-definition> --- Tells the client to use another service definition file than 'default.xml'. The service definition file must be placed in the ~/sclient directory at the M&C server
- -o --- Enables automatic pop ups of the fault list window with every new fault.
- -r <seconds> --- Enables the automatic reconnect feature. Should not be used directly,

the MasterClient application makes use of this switch.

- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -v --- Suppresses the program version match check on startup
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.

VioIP Client

The VioIPClient client program is invoked by a command line looking like this:

java -cp client.jar satnms3.vioip.VioIPClient [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -g <group-ip> --- Defines the group to be displayed by this client instance. Expects the group ID (not the name) as a parameter. This parameter is mandatory to make the program work, the group ID cannot be set or changed at the GUI.
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -n 1 -n 2 -n 3 --- Tells the client how to treat "new faults". Without the -n option, new faults are not reported separately. The fault indicator in the main window's toolbar ia active while the server's summary fault is active.
    - **n1** --- The program treats new faults separately. A fault is new until an operator acknowledges it by clicking into the fault indicator or by acknowledging the fault in the event log or event report window. The new fault is displayed as a red mark labeled "NEW FAULT". If the fault disappears without being acknowledged, a gray "NEW FAULT" mark is shown.
    - **n2** --- Behaves like **-n 1** , but makes the program ring the keyboard bell while a new fault is pending.
    - **n3** --- Works like the previous, but suppresses the very first "NEW FAULT" after the start of the client. New faults which occurred while the client program did not run are not signalled, nor are gray "NEW FAULT" conditions. Only new faults recognized while the client program runs are shown.
- -q --- Suppresses some alerts like 'connection broken' and others.

- -r <seconds> --- Enables the automatic reconnect feature. Should not be used directly, the MasterClient application makes use of this switch.
- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -v --- Suppresses the program version match check on startup
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.

VioIP Configurator

The VioIPConfigurator program usually is invoked with a button click from the VioIPClient program. Beside this, it also may be invoked as a stand alone program by a command line looking like this:

java -cp client.jar satnms3.vioip.VioIPConfigurator [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation provides name resolution for this address.

The following command line options may be used with the program:

- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -s --- Suppresses the splash screen.
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -q --- Suppresses some alerts like 'connection broken' and others.
- -d <r,g,b> --- Sets the foreground color of disabled texts / elements in the GUI. r,g,b are numbers in the range 0..255, comma separated, specifying the RGB components of the color.
- -v --- Suppresses the program version match check on startup
- -V --- Tells the program to be verbose on the command line. This option is for debugging only, **never** set it for operational use.

CDB Table Editor

The CDB Table Editor program usually is invoked with a button click from the M&C Client program. Beside this, it also may be invoked as a stand alone program by a command line looking like this:

java -cp client.jar satnms3.gui.CDBTableEditor [options ...] <IP address of the server>

The IP address of the M&C server may be replaced by a host name if your network installation

provides name resolution for this address.

The following command line options may be used with the program:

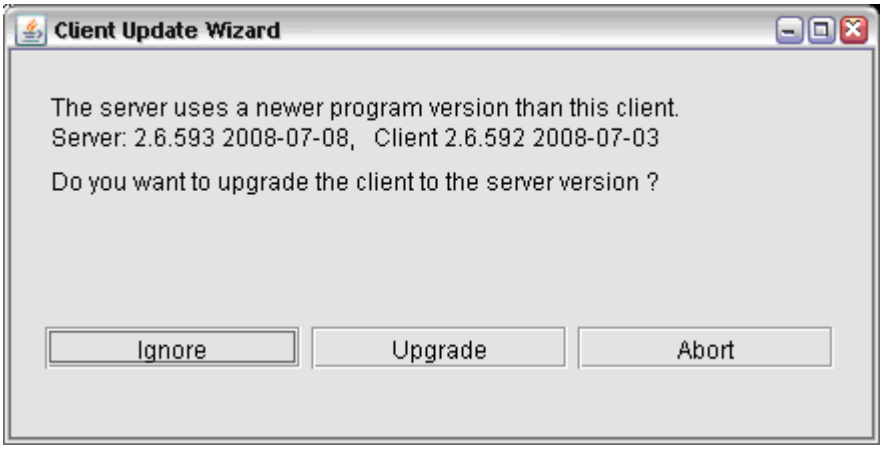
- -u <user-name> --- Specifies the user name for autologin. Must be used together with -p
- -p <password> --- Specifies the password for autologin. Must be used together with -u
- -s --- Suppresses the database selector widget in the toolbar.
- -l <look-and-feel> --- Lets you set the "look and feel" of the user interface to one of several definitions. Accepted values are: Aero, Fast, Aluminium, McWin, Luna, Pulsar, Noire, Mint, Graphite, Smart, Bernstein, Acryl and HiFi.
- -db <db-name> --- Selects the database to be edited. Default is 'channels'.

4.1.4 Automatic Software Update Of The Client

The sat-nms Client Software (version 2.6.591 and above) includes an automatic check for updates. After startup the client connects to the NMS server and compares the software versions. Client and server should always run the same version of the sat-nms software. The software update feature also supports a downgrade of the client software, e.g. if the server has been restored from a backup with an older software version.

Upgrade

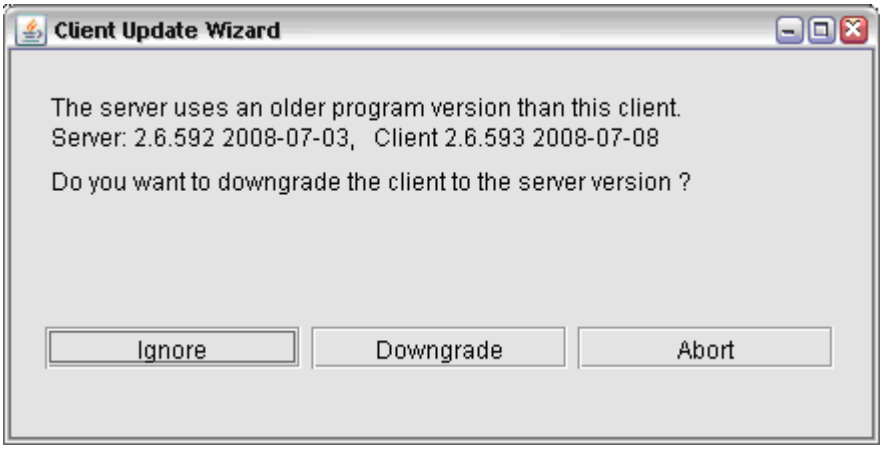
If the NMS server is running a newer version of sat-nms you can upgrade the local client to this version.



- Ignore: --- This ignores the version discrepancy and you will working with the already installed client program.
- Upgrade: --- The newer client program will be installed on the local machine
- Abort: --- Aborts the client program, cancels the program download

Downgrade

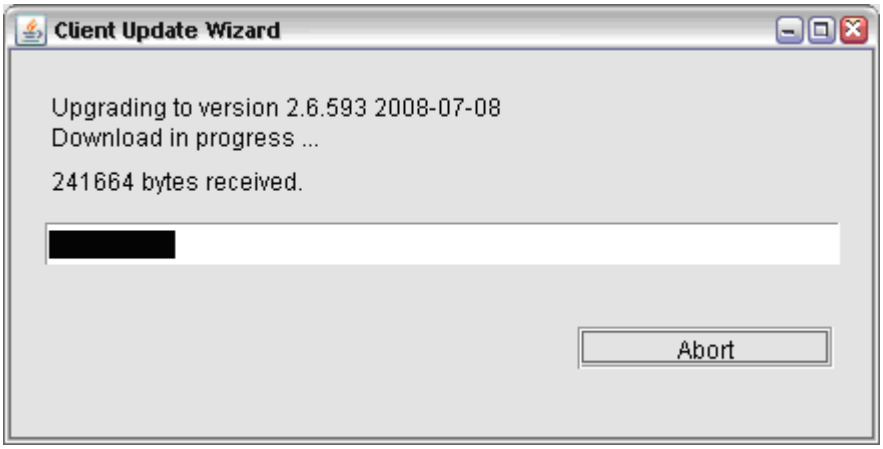
If the NMS server is running an older version of sat-nms you can downgrade the local client to this version.



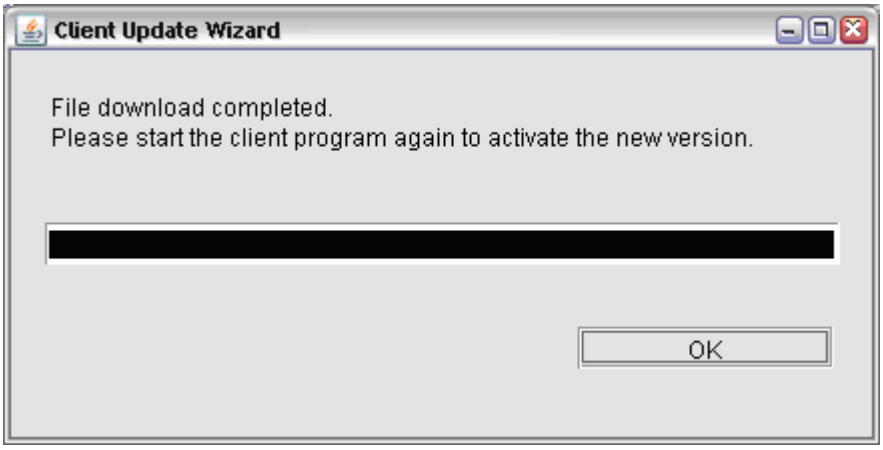
- Ignore: --- This ignores the version discrepancy and you will working with the already installed client program.
- Downgrade: --- The older client program will be installed on the local machine
- Abort: --- Aborts the client program, cancels the program download

Download process

After pressing the upgrade or downgrade button, the software starts the download of the client program from the server to the local machine. With a LAN connection this takes only a few seconds, if you are connected through a dial up connection may take somewhat longer.



You may cancel the download at any time by clicking the 'Abort' button. After successfully downloading the software displays a message and after selecting OK the client program will be closed.



Now simply restart the client again as described in chapter 'start client' and you will work with the upgraded or downgraded version.

4.2 Configuration Files

The satnms M&C software provides a number of configuration files which control wide aspects of the functionality of the software files all use an easy to read and mostly self explaining format. The files explained in the following chapters are:

- backend.properties: This file is located in the base directory of the satnms backend installation. It controls the behavior of the backend server.
- user-ip-restrictions.json: This file is also located in the base directory of the satnms backend installation. It controls which user may login to the backend from which machine.
- vlc.properties: This file is located in the base directory of the satnms M&C installation. It controls all important parameters of the M&C server.
- client.properties: This file also is located in the base directory of the software. It is read by every legacy Java client connecting to the server. It controls important aspects of the client software's behavior.
- satnms.rc: Controls the startup of the satnms software and programs which have to be initialized before the M&C server itself can be started.
- system.name: Defines the name of the M&C system
- traprec.json: Controls the behavior of the SNMP trap receiver built into the software.

4.2.1 backend.properties

The backend.properties file controls the configuration of the backend server. How many and which M&C systems are controlled by the backend, how to authenticate at the backend and some debugging options are defined in this file. The backend.properties file is read once by the software on startup, so any changes to this file become effective with the next start of the backend. The backend installation package contains a backend.properties.default file which can be used as a template to setup a new properties file from scatch

Controlled M&C systems

For every M&C system controlled by the backend, at least two parameters must be set: The M&C system's IP address (`backend.mnc.*.ip`) and it's name (`backend.mnc.*.name`). Example for the first M&C:

```
backend.mnc.1.ip=127.0.0.1
backend.mnc.1.name=MNC
```

M&Cs are numbered 1,2 ... n, number 1 is called the primary M&C. It must always exist, the backend uses it to get screens, driver definitions and to authenticate users during the login. The name of each M&C should match the name which is set at the M&C server itself. This ensures that the M&C name presented at the UI frontend matches the M&C name appearing in event log messages.

The backend supports redundant M&C pairs, monitors and control the switchover. To define a redundant M&C pair, some more parameters are required. They are the IP address of the backup M&C and some timing parameter controlling the switchover process.

```
backend.mnc.2.ip=192.168.2.229
backend.mnc.2.name=MNC-2
backend.mnc.2.backup.ip=192.168.2.227
backend.mnc.2.backup.retries=3
backend.mnc.2.backup.delay=15
```

As soon as `backend.mnc.*.backup.ip` is defined for a M&C, this is considered to be a redundant pair. The `backend.mnc.*.backup.retries` parameter defined how many reconnect attempts to the primary M&C shall be made until a switch over is done. `backend.mnc.*.backup.delay` specifies the wait time between connection attempts.

EventDB server

The backend needs to know where the event database is hosted. The IP address is specified with:

```
eventdb.server=127.0.0.1
```

For small installations this is typically the same machine as the backend

SQL database access

The backend stores information about satellites, satellite channels and antenna pointings in SQL a database. The setings below specify how to access this database. Again in a small installation the database will run on the same host as the backend itself.

```
db.satlist.host=127.0.0.1
db.satlist.user=satnms
db.satlist.password=satnms
db.satlist.usessl=false
```

The backend may use a redundant database configuration where the primary database server is configured r/w and the backup server is r/o. For such a configuration the `db.satlist.host` parameter defines the primary and backup server addresses separated by a comma. The first address denotes the primary database server.

```
db.satlist.host=192.168.0.100,192.168.0.101
db.satlist.keep=300
```

The `db.satlist.keep` parameter defines the time (secs) after which the backend cuts a connetion to the backup server in order to try if the primary one is available again.

Inventory database

The inventory database is part of the SQL database which also stores satellite channels etc. The inventory feature must be enabled explicitly by setting the parameter below to true:

```
db.inventory.enabled=false
db.inventory.debug=false
```

The `db.satlist.*` parameters shown in the section above this must also be setup properly to enable the inventory database. Setting the debug flag *true* lets the software print out all SQL traffic regarding the inventory into the .panic.log file. This causes huge log files, therefore shouls be used only investigating problems, not during normal operation.

OAuth2 authentication

The backend uses OAuth2 to authenticate API calls. it provides a local authority which issues tokens for local logins. The parameters below configure the behavior of this feature

```
oauth2.access.token.valid.time=3600
```

Specifies the time a token is valid (seconds). default is 3600

```
oauth2.refresh.token.valid.time=7200
```

Specifies the time the refresh token is valid (seconds). default is 7200

```
max.sessions.total=0
```

Specifieds the max. number of session which totally may be open at the same time (default 0, means don't care)

```
max.sessions.user=0
```

Specified the max. number of session which may be open at the same time for the same user (default 0, means don't care)

The backend accepts JWT tokens from an external authentication authority if the following parameters are set URL to access the JWKS from this authority. default is empty.

```
oauth2.jwk.provider=
```

The parameter below secifies IP address of an HTTP(s) proxy if the JWKS provider shall be accessed thru this proxy. default is empty (no proxy)

```
oauth2.jwk.proxy=
```

The parameter below specifies the AD group name to privilege level look up list. It consists of group-name:privilege-level pairs, separated by comma characters. default is an empty list.

```
oauth2.groups=SATNMS-ADM:150,SATNMS-OP:110
```

Beside from the "Authentication" header the backend may read the JWT token from a cookie coming with the API call. default is mpty (don't accept JWT from a cookie)

```
oauth2.cookie.name=
```

LDAP local login

For local logins the backend may look up the credentials of a user at an LDAP directory server instead of parsing the `.users` file from the primary M&C. The settings below are used to specify how to access the LDAP server and how to interprets the data read from there:

```
ldap.enable=yes
ldap.url=ldaps://ad.mydomain:636
ldap.default.domain=ad.mydomain
ldap.search.user=searchsatnms
ldap.search.password=searchsatnms
ldap.groups=SATNMS-ADM:150,SATNMS-OP:110
ldap.keystore.name=ldap.p12
ldap.keystore.password=satnms
```

Debug settings

The backend offers a number of parameters which enable extensive logging of certain events, internal messages of parameter updates for debugging purposes. For normal operation you should keep the disabled all because log files can become very large with debuggin enabled. Debugging also may reduce the performance of the backend.

The parameter/status communication to a specific M&C may be logged by setting this parameter true (replace '*' with the index of the M&C to switch to verbose.

```
backend.mnc.*.verbose=true
```

Setting this true logs every message sent over a websocket. Creates a huge amount of log data, logs are better to interpret if only one single frontend with one window is connected to the backend

```
websocket.verbose=false
```

Setting the parameter blow to true logs m&c connect/disconnect events.

```
websocket.logConnected=false
```

Setting the parameter below to true logs the oauth2 authentication process for every API call in detail.

```
oauth2.verbose=false
```

The parameter below controls logging for LDAP logins. Please note that this setting expects 'yes' to be activated.

```
ldap.verbose=no
```

4.2.1.1 Example configurations

MNC and Backend services on same host (all-in-one installation)

This is a very simple configuration running backend and MNC service on the same host without any additional features:

```
# MNC server
backend.mnc.1.ip=127.0.0.1
backend.mnc.1.name=MNC

# EventDB server
eventdb.server=127.0.0.1
```

Two MNC systems and a backend server on different host

This setup includes 3 different hosts:

- One central server running the backend service, event database SatDB datbase.
- Two hosts running the MNC service.

The backend service connects via network to the MNC services on both host. And the MNC services deliver their events to the central server and using the SatDB on the central server.

```
# MNC servers
backend.mnc.1.ip=10.16.2.1
backend.mnc.1.name=UPLINK-TP1
backend.mnc.2.ip=10.16.2.2
backend.mnc.2.name=UPLINK-TP2

# EventDB server
eventdb.server=10.16.2.21

# SatDB server
db.satlist.host=10.16.2.22
db.satlist.user=postgres
db.satlist.password=mysecretpassword
db.satlist.usessl=true
```

backend server controlling redundant MNC systems

This setup includes also 3 different hosts:

- One central server running the backend service, event database SatDB datbase.
- A redundant pair of MNC services (Main and Backup)

The backend service connects via network to both hosts and control which one is the currently active MNC service. The backend services monitors the availability and stops & starts the MNC services on the hosts as required.

The active MNC service delivers its events to the cental EventDB server

```
# MNC servers
backend.mnc.1.ip=10.16.2.1
backend.mnc.1.name=UPLINK-TP1
backend.mnc.1.backup.ip=10.16.2.2
backend.mnc.1.backup.retries=3
backend.mnc.1.backup.delay=30

# EventDB server
eventdb.server=10.16.2.21
```

4.2.2 user-ip-restrictions.json

If the backend finds this file at startup, it restricts the access to the backend following the rules defined in this file. The rules in the file describe which user may login to the backend from which client machine. This applies to WebUI logins, not to operation system level (ssh) logins.

IP based login restrictions be defined in two ways:

1. From a given client IP address (or subnet) only a defined set of users may log in.
2. A given user may login only from a defined set of IP addresses or subnets.

While these restrictions at the first glance sound quite similar, the consequences of these restrictions may be completly different. A type 1 rule is used to exclude all users who are not listed in the rule, a type 2 rule exludes all non listed locations for a particular user.

The user-ip-restrictions.json file uses JSON to describe the rules to be applied. Example:

```
{
   "comment": "Example rules file",
   "ip_sources": [
      {
         "source_address": "10.10.21.0/24",
         "allowed_users": ["peter","paul","mary"]
      },
      {
         "source_address": "192.168.0.144",
         "allowed_users": ["guest"]
      }
   ],
   "users": [
      {
         "username": "john",
         "allowed_addresses": [ "10.10.1.0/24", "192.168.2.0/24" ]
      }
   ],
   "default_behavior": "grant"
}
```

The array "ip_source" contains the list of type 1 rules. Each rule defines an IP address or subnet and the list of users who are permitted to login from this network location. In the example above, from the subnet "10.10.21.0/24" only the users "peter","paul" and "mary" are permitted to login. all other users are rejected when trying to login from this subnet, even if they entered valid credentials. The second rule in this list limits the login from the IP "192.168.0.144" to the user "guest".

The array "users" contains the list of type 2 rules. In this example there is only one rule define which limits the login for user "john" to the subnets "10.10.1.0/24" and "192.168.2.0/24". Login attempts for "john" will be rejected unless the IP address of his computer is in one of these subnets.

Finally, the definition "default_behavior" tells how to deal with users who are not covered by any rule above. Valid options are "grant" or "deny".

The file may contain type 1 and type 2 rules at the same time or only one of the arrays "ip_source" or "users". For example only one client machine may be limited to a certain user:

```
{
   "comment": "Example rules file",
   "ip_source": [
      {
         "source_address": "192.168.0.144",
         "allowed_users": ["guest"]
      }
   ],
   "default_behavior": "grant"
}
```

This file only limits the Browser at "192.168.0.144", only user "guest" may login from here. Other users are rejected when logging in from here, but they may login from any other source.

If the user-ip-restrictions.json file does not exist, not IP based login restrictions are applies. user-ip-restrictions.json uses strict JSON syntax, any comments in the file must be coded as definitions which are ignored by the parser (e.g. "comment":"...").

4.2.3 vlc.properties

Defines some general configuration settings of the VLC/M&C Server, some of them may be defined on the command line, too.

Timezone settings

By default the sat-nms software displays all timestamps in UTC. you may change this with the timezone parameter. IF CHANGED, THE PARAMETER MUST BE CHANGED IN BOTH, vlc.properties AND client.properties TO THE SAME VALUE !!

With a NMS system, the timezone for NMS, all VLCs and all clients MUST be UTC, the timezone parameter must not be defined !!

```
## Examples for non-UTC time zones:
## timezone=GMT+03
## timezone=GMT-10
```

SNMP exceptions

Print exceptions for SNMP communication usefull for debugging SNMP. Default is `no`. Exceptions will be logged to `.panic.log`

```
showSNMPExceptions=no
```

Catch Exceptions

Print more/all exceptions for SNMP communication usefull for debugging SNMP. Default is `no`. Exceptions will be logged to `.panic.log`

```
showCatchedExceptions=no
```

Startup debug

`yes` makes the software to log in detail what it does during startup Default is `no`. Messages will be logged to `.panic.log`

```
## startup.debug=yes
startup.debug=no
```

Procedure debug

Setting to `true` adds additional information to the output of verbose mode. It shows at the beginning of a driver cycle which procedures are marked as "to be excecuted" (dirty) with a timestamp and it show when these procedures are executed.

```
## procedures.debug=true
procedures.debug=false
```

Remember to the set verbose mode of the device to `true` if you want to see the additional information.

Example:

```
                        GET procedures 9 12 marked dirty 14:25:35.263
                                running procedure 9 14:25:35.264
tx(BCRX-1): /read?levl=?
rx(BCRX-1): levl=-77.45
 BCRX-1.power=-77.45
                                running procedure 12 14:25:35.493
tx(BCRX-1): /rmt?sact=?
rx(BCRX-1): sact=0
 BCRX-1.ssrch.active=0
```

Startup Delay

Adds a delay between the initialization of two device threads. Value in msecs, default 0.

```
startup.delay=100
```

Communication timeout *deprecated*

The communication timeout to be used for tty over ip connections in msecs, Default 2000. This setting is *deprecated* because the timeout can be configured via `Device-Window > Maintenance Page > Serial > Timeout` individually for each device.

```
tty.ip.timeout=2000
```

TCP/IP interface definitions *deprecated*

Defines interfaces to control devices via tcp/ip. This is deprecated because it can be easily defined via client `Device Setup Window`. There is no need anymore to define `ttyNx` pseudo-interfaces.

```
```

Local event database

If set to 'yes' the server starts it's own event database. This is for stand alone M&C systems.

VLC's integrated to a NMS don't use a local event database, they send the messages to the central event database on the NMS server instead. Also MNCs working with a common Event Database, don't use a local event database.

By default, the command line switch `-e` in `/home/satnms/satnms-start` will already enable a local event database if `SATNMS_TYPE="mnc"` in /etc/satnms.rc is set to `mnc`.

```
```

Duplicate events

If set to `yes` on a MNC system sending it's event messages primarily to a central event database, the message are also duplicated to a local event database. Default is `no`.

To make this work, `local.edb` must be set to `yes` as well.

Never set `duplicate.edb=yes` for a stand alone MNC system. All messages will appear twice in the event log!

```
duplicate.edb=yes
```

EventToSerial AddOn

AddOn for fault messages reports to external systems:

- satnms.addon.EventToSerial: sends text messages to serial interface
- satnms.addon.EventToMail: sends text messages to mail recipients
- satnms.addon.EventToScript: calls a user defined script on selected events

Both needs additional configuration in separate configuration files.

```
server.addon=EventToSerial
server.addon=EventToMail
server.addon=EventToScripts
```

Serial Control Port

To control the VLC/MNC remotely via a serial interface set this option to a valid port name. Don't use this port to control a device at the same time.

```
server.rcontrol.port=/dev/ttyS1
server.rcontrol.baudrate=9600
```

Network Control Port

The VLC/MNC server provides a SSL remote control port (read-write) at port 2015, a TCP remote control port at port 2016 (read-write) and a second one at port 2017 (read-only). To switch off either of these ports comment out the appropriate line.

```
server.rcontrol.ssl.read-write=yes
server.rcontrol.tcp.read-write=yes
server.rcontrol.tcp.read-only=yes
```

Build-in WebServer

Setting this true makes the built in web server on TCP port 2002 require the user to login with a valid user/password combination in order to see / modify the parameter tree.

```
http.requiresAuthentication=true
```

TimeSync with NMS server

The following entry specifies the behavior of the server when it detects that the VLC clock is more than 30 seconds off the NMS time. Three settings are possible:

- FAULT : A fault of the SYSTEM device is generated (default)
- LOG : The time difference is logged as a INFO message to the event log
- IGNORE : The time difference is ignored completely

Only required in NMS environment where no NTP service is available.

```
server.nms.clockdiff=IGNORE
```

Default Help Page

To configure the main help page set this option to the name of the html-page without any directory or file extension. The main help page is the page that appears when clicking the help button in the main screen. default: 2210

```
help.topic=4520
```

Channel database

The CDB client in the software is preconfigured to work in a VLC/NMS configuration. The CDB server is located at the NMS in this configuration, the connection to the CDB is *online* while the

VLC *online* from the NMS' point of view.

Beside this, two other configurations are possible: A MNC can run it's own CDB server as a self contained solution or multiple MNC servers can share a CDB running on one of them.

A MNC running a CDB server must set this to `true` . `false` disables the local CDB server

```
## cdb.localOnly=true
cdb.localOnly=false
```

A MNC which wants to use the CDB running on another MNC must uncomment this line with the IP address modified to the address of the M&C running the CDB server.

```
cdb.externServerAddress=192.168.2.214
```

Setting this true, enables some magic when editing channel names in the RX-LineSettings-CDB-KSC device: Channel names automatically get a signature containing the DVB-mode, the symbol rate and the RX pol appended. In the channel editor page this signature is not visible.

```
## cdb.LineSettings.magicname=true
cdb.LineSettings.magicname=false
```

If present, these entries make the channel / biss-key databases sync the local backup to the central database in the NMS in regular intervals. The time interval is defined in hours (floating point).

It is disabled if cdb.localOnly=true

```
## cdb.channels.syncInterval=24.0
## cdb.bisskey12.syncInterval=24.0
## cdb.bisskey16.syncInterval=24.0
```

settings for CSM spectrum analyzers

Switches the preamp for a LPTech LPT3000RX4 spectrum analyzer ON/OFF affects all LPT3000RX4 controlled by the M&C, default is preamp ON

```
csm.lpt3000rx4.preamp=ON
```

This setting is deprecated, it refers to the outdated CSM-Spectrum-Analyzer device. Actual spectrum analyzer drivers handle this internally

Universal SNMP agent

The following entries refer to the universal table based snmp agent listening at UDP port 2261.

Defaults are:

```
snmp.agent.enable=no
snmp.agent.readCommunity=public
snmp.agent.writeCommunity=private
snmp.agent.trapTargets=
```

`trapTargets` is a space separated list of IPv4 addresses, each optionally followed by a colon and a port number. for entries without port number port 162 is assumed.

Example:

```
snmp.agent.enable=yes
snmp.agent.readCommunity=public
snmp.agent.writeCommunity=private
snmp.agent.trapTargets=192.168.0.89:2162 127.0.0.1:2162
```

User configurable SNMP agent

The following entries refer to the user configurable snmp agent listening at UDP port 2161.

```
snmp.max.oid=1000
```

The agent gets initialized if a snmp.setup file exists. The agent limit the number of OIDs it creates from the snmp.setup file. The default limit is 1000 ans may be changed uing the parameter shown above.

UDP Heartbeat

These entries control the UDP heartbeat sent by a VLC to make the NMS recognize that the VLC is reachable in the network. To activate the heartbeat, set `udp.heartbeat.enabled=true`

The interval generally should not be changed. It is given in msecs, it should be set to one third of the timeout value set at the NMS.

```
udp.heartbeat.enabled=false
udp.heartbeat.enabled=true
udp.heartbeat.interval=5000
```

logParameterChanges

If set true, event log messages indicating parameter changes (logParameterChanges set true for a device) also contain the name and the IP address of the initiator of the parameter change. default is false for backward compatibility

```
## log.initiator=false
log.initiator=true
```

Prologix debug

Enable debug output for ProLogix GPIB to Ethernet converter. Disabled by default.

```
prologix.debug=false
```

Macro Scheduler

If set true, the macro scheduler automatically deletes outdated events. if false, these events remain in the schedule and can be viewed in the GUI. Default is true.

```
## scheduler.autodelete=true
scheduler.autodelete=false
```

Client Queue Size

This entry configures the client queue size (number of messages). Default value is 10000, the value which was set before as fixed size.

```
clientpeer.queueSize=50000
```

Port binding

By adding a line `bind.xxxx=a.b.c.d` the server socket at port `xxxx` can be bound to a specific address / interface

works fo the following port numbers

Port	Service
2000	Debug terminal
2001	Server-Client message transfer
2002	HTTP webserver (deprecated)
2003	M&C server control
2004	EventDB feed
2005	Live event log
2006	EventDB query
2007	JFTP data transfer

4.2.4 client.properties

Several aspects of the client behavior can be configured in the text based configuration file `/home/satnms/client.properties`. The following chapter descripes the different option and

related functionalities.

All chances in this file we be applied for every client which connects to the server after this configuration file was written.

Addressing users and hosts

All keys in this file may be prepended by a user name (the user name to log into the sat-nms GUI) or a host name. If the value for a key 'some.key' is searched, the software first tries 'user.some.key' where 'user' is replaced by the current user's login name. If this key was not found, it tries 'hostname.some.key' where hostname ist the client's host name as reported by the operating system. If this also fails, the as the last fall back the plain key is searched.

This search method gives the capability to overwrite some client properties for specific users or client hosts.

Examples:

```
## disable edit/take mode for client with hostname "pc1":
pc1.gui.useEditTake=false

## disable edit/take mode for sat-nms user "user1" on any client pc:
user1.gui.useEditTake=false
```

Time zone settings

By default the sat-nms software displays all timestamps in UTC. you may change this with the timezone parameter. IF CHANGED, THE PARAMETER MUST BE CHANGED IN BOTH, vlc.properties AND client.properties TO THE SAME VALUE !!

Examples for non-UTC time zones:

```
timezone=GMT+03
timezone=GMT-10
```

Exclusive login

Setting this true enables _exclusive login*, meaning that only client may be logged in at a time.

```
login.exclusive=false
login.exclusive=true
```

When trying to login on a system with enabled *exclusive login* and there is already another user logged in, the login dialog will report this with the message* `another client is logged in` *and gives you the option to *FORCE* your own login and kick out the connected user. Forcing login is only possible with an administrator account (privilege level 150)*

Primary client

Setting this to an IP address of a certain client computer gives this client instance an exclusive priority: no other client may force the log out of the primary client, but the primary client may log out any other client.

This option is meaningful only if login.exclusive=true

A typical application scenario is, that a client installed at the antenna site should be able to block a remote connected users.

```
login.primary=192.168.0.101
```

Automatically timed logout

Setting this to a value greater 0 enables automatically logout of users sat-nms client users after the given number of minutes of (user-) inactivity.

To make special setting for a given user or host add username or hostname in front of autologout parameters. By default this automatically logout is disabled (0).

Example disable autologout for user _operator* but set it to 5 minutes for all others:

```
## other users
 operator.autologout=0
 autologout=5
```

Device list windows access level

The privilege level necessary to open the device list in the toolbar in the VLCFrame / MCFrame windows. Default required privilege level to open the device list windows is 100 (operator).

```
devicelist.privilege=110
```

Config parameter access level

The privilege level necessary to change device setup parameters at the maintenance / setup window.

Default is 150, select a lower number will allow different users than normal administrators to change these settings. Recommendation is to define users with level 140.

```
configParameters.privilege=140
```

Macro scheduler access level

This defines the privilege level necessary to edit the schedule of the system macro scheduler.

```
scheduler.privilege=110
```

Screen element background color

True makes the configured background color of disabled screen elements override the system 'disabled' background. Works only with entry fields, read-only fields and with the searchable drop down list field.

```
gui.overrideBackground=true
```

Look and feel of read-only elements

True lets read-only elements look "enabled" even if the operator is not logged in. This is the way, satnms2 did show read-only fields. Default is *false*

```
gui.keepReadOnlyEnabled=true
```

Edit/Take mode

True makes the user interface use the edit/take mode for all device screens. This option change the behavior of device screens. With enabled edit/take mode commands will be not send directly if you enter a new value or select a dropdown entry. But all device windows will show 2 additional buttons : EDIT and TAKE.

The EDIT button enables all read/write parameter fields to change the values and the TAKE button send all changed parameters to the device.

By default this mode is disabled.

```
gui.useEditTake=true
```

**Event sort order*

True makes the event report and event log windows sort recent fault messages first (on top). Default is *false*.

```
gui.eventSortRecentFirst=true
```

Fault list window background color

If set *true*, in the fault list window warnings are shown with a yellow background, faults with a red background (may be changed by a toolbar button of the window)

```
gui.faultListColored=true
```

Fault list window line color

If set *true*, the fault list window sorts the lines fist by device, then by time (may be changed by a toolbar button of the window)

```
gui.faultListByDevice=true
```

Suppress warnings fault list window

If set true, the fault list window suppresses all warnings (may be changed by a toolbar button of the window)

```
gui.faultListSuppressWarnings=true
```

Suppress signal on emblem

True prevents device icons showing the 'signal on' emblem, even if the device state is recognized as 'signal on' and an image file for the emblem has been found.

```
gui.suppressSignalOnEmblem=true
```

New fault popup

If set true, each new fault makes the fault list window pop up (or come to front). applies only to the M&C client. The -o command line switch of satnms3.gui.MCFrame has the same effect.

```
gui.faultListPopUpOnNewFault=true
```

Show tree view button

True makes the M&C client window show a toolbar button to launch a tree view window, false suppresses this button. This feature is enabled by default, the tree view button is shown if this definition is missing

```
gui.showTreeViewButton=true
```

Tree view default device icon

The treeview client/window uses this device icon to build dynamically generated device screens.

```
gui.treeview.dynamicDeviceIcon=device-rectangle.gif
```

Alternative Switch icon set

Define different switch icons for the screen editor

```
gui.editor.predefinedSwitch.1=cwgswitch
gui.editor.predefinedSwitch.2=cwgswitch-mirrored
gui.editor.predefinedSwitch.3=ccxswitch
gui.editor.predefinedSwitch.4=ccxswitch-mirrored
gui.editor.predefinedSwitch.5=clswitch
gui.editor.predefinedSwitch.6=crswitch
```

VLC player integration

The full path of the VideoLAN media player. Required to run the VLC player on Windows client machines from a "VideoLAN" frame button.

Backslashes must be doubled, the whole path must be enclosed in double quotes if it contains spaces. You can also defined this setting by host to target client PCs with different operating systems.

```
videolan.exe="vlc.exe"
videolan.exe="C:\\Program Files (x86)\\VideoLAN\\VLC\\vlc.exe"
```

Event DB

Defines the IP Address of the EventDB Server used by the client to show the Eventlog. This is usually *not* configured: The Client will use the IP address of the MNC server.

In case the EventDB is not available locally on the MNC server but on any other machine you can configure here the IP address of the "external" EventDB Server.

```
eventdb.server=10.10.1.111
```

4.2.5 satnms.rc

working mode

Select between operation as MNC server (mnc) or together with an NMS Server (vlc)

```
SATNMS_TYPE="mnc"
```

serial ports

Moxa PCI Express cards did not have any jumpers to select RS232/422/485 and termination. This has to be set with `muestty` on startup.

Servers with OS Debian-satnms-4 and later supports 1 card with up to 8 ports. Define here the existing ports and interface types:

```
## add 2 lines for each port and replace "x" with the number 1..8
SATNMS_SERIALx_INT = [RS232,RS422,RS4852W,RS4854W]
SATNMS_SERIALx_TERM = [NONTERM,120TERM]
## (only relevant for 422/485)

## example Port 1 to RS422 and no termination
SATNMS_SERIAL_INT_1=RS422
SATNMS_SERIAL_TERM_1=NONTERM
```

Please refer to Moxa documentation for details. Check current settings with

```
muestty -g /dev/ttyS11
```

Card comes up with RS232, therefore it is not necessary to configure these cards. Just comment out lines with RS232 to prevent error messages.

4.2.6 system.name

Add one line (text) which should be shown in the window title of the sat-nms MNC Java Client. Default is `sat-nms MNC Monitoring & Control System`

Examples:

- Antenna 1 M&C
- MNC Teleport Steisslingen

4.2.7 traprec.json

This file configures the trap receiver built into the M&C server. The trap receiver is used to call `PROC ASYNC TRAP` procedures in selected devices / device drivers on every received SNMP trap. The trap receiver is started if this file is present and can be parsed successfully.

File Syntax

The file uses JSON syntax to define the traprec configuration in a structured way. The elements of the JSON document are explained best by example:

```
{
   "comment": "sat-nms SNMP trap receiver configuration",
   "general": {
      "listenPort": 2162,
      "logToStdOut": true,
      "logToEdb": false,
      "trapCommunity": "public"
   },
   "snmpv1": {
      "enabled": true
   },
   "snmpv2c": {
      "enabled": true
   },
   "snmpv3": {
      "enabled": true,
      "users": [
         {
            "name": "secretname",
            "authpass": "AuthPassword",
            "authentication": "MD5",
            "privacy": "NONE",
            "privpass": "PrivPassword"
         }
      ]
   }
}
```

general

The *general* section defines some general properties of the trap receiver. The definitions in this section are:

name	type	default	description
listenPort	integer	2162	The port number to listen at. The valid range for this is 1024 to 65535. If you require the trap receiver listen at the standard port 162, you should setup a port forwarding to 2162 for this.
logToStdOut	bool	false	If enabled, every received trap gets logged to stdout (to the .panic.log file). The complete trap information as available in the PROC ASYNC TRAP procedures ist logged. This is useful for debugging which traps are sent by a device.

name	type	default	description
logToEdb	bool	false	If enabled, every received trap gets logged in the M&C event log.
trapCommunity	string	null	If set, the trap receiver accepts only traps which match the given trap community (SNMPv1 and SNMPv2c only)

snmpv1

The *snmpv1* section contains a flag to enable or disable SNMPv1 at the trap receiver.

name	type	default	description
enable	bool	false	*true* enables SNMPv1

If disabled, the trapreceiver ignores all SNMPv1 traps it receives.

snmpv2c

The *snmpv2c* section contains a flag to enable or disable SNMPv2c at the trap receiver.

name	type	default	description
enable	bool	false	*true* enables SNMPv2c

If disabled, the trapreceiver ignores all SNMPv2c traps or inform messages it receives. SNMPv2c inform messages are not acknowledged by the trap receiver if SNMPV2c is disabled.

snmpv3

The *snmpv3* section contains a flag to enable or disable SNMPv3 at the trap receiver and the list of authenticaed users the trap receiver accepts.

name	type	default	description
enable	bool	false	*true* enables SNMPv3
users	array	-	a list of user definitions (see below for details)

If disabled, the trapreceiver ignores all SNMPv3 traps or inform messages it receives. SNMPv3 inform messages are not acknowledged by the trap receiver if SNMPV3 is disabled.

users

If SNMPv3 is enabled, the *snmpv3* section must contain a *users* array with at least one element. SNMPv3 does not work without a user definition, even in noAuthNoPriv mode. The definitions

for one user are:

name	type	default	description
name	string	-	The secret name of the user.
authpass	string	-	The user's pass phrase, this is required if *authentication* is not "NONE"
authentication	string	"NONE"	The authentication mode, one of "NONE", MD5" or "SHA". "NONE" implies noAuthNoPriv mode, *privacy* is ignored in this case.
privacy	string	"NONE"	The privacy mode, one of "NONE", "AES" or "DES".
privpass	string	-	The privacy pass phrase, this is required if*privacy* is not "NONE"

The *name* definition is mandatory for a user as well as the*authentication* and *privacy* definitions. The pass phrase definitions are only required if *authentication* and/or *privacy* are enabled.

4.3 Event Database Configuration and Event Notification Add-Ons

Basic EDB settings

The Event Database basic configuration (e.g. if the EDB should be started on a MNC system) is defined in `/home/satnms/vlc.properties`. Please refer to the chapter vlc.properties for details.

EDB settings in the SYSTEM device

There are also settings regarding the Event Database (e.g. IP address of the EventDB Server) which needs to be configured in the SYSTEM device

EDB.properties

Event Database properties are definesin the `/home/satnms/edb/EDB.properties` file. Page EDB.properties describes this feature in detail.

Event Notification Add-Ons

There are two add-ons which may be configured with the M&C software to notify operators if new event messages have been issued by the system. Notification may be through a RS232 serial interface of the M&C server or by E-mail. Event notification add-ons are available for sat-nms M&C systems only, not for the NMS server.

Event To Serial Notification

The event to serial notification add-on sends event messages through a serial RS232 interface.

This interface may be connected to a separate unit which sends SMS messages or teletype messages from this information. Page Event To Serial Notification describes this feature in detail.

Event To Mail Notification

The event to mail notification add-on sends event messages as e-mail notifications to one or more recipients. Page Event To Mail Notification describes this feature in detail.

Add-On Configuration

A notification add-on is activated by setting the key "server.addon" in the file "vlc.properties" either to "EventToSerial", "EventToMail" or to "EventToScript". All particular settings for the selected notification add-on are defined in a separate configuration file. A file called "rules" has to be created with the filter rules which messages are to be forwarded and which not.

The "rules" File

All event notification add-ons provide a filter function for the event messages to forward. Using filter rules defined in the file "rules", the software forwards only messages which match one of the rules specified in the "rules" file.

This file is a plain text file containing one rule per line. Empty lines and comment lines (starting with a '#'-character) are ignored. Each rule has the format <device-name>:<text-pattern>, where both parts may be replaced by "*" as a general wildcard. A rule matches, if the event source matches the given device name and if the message text contains the given text pattern.

Here some example rules:

```
HPA-1:FAULT          matches messages from HPA-1 containing
                   "FAULT" in the event message text.

HPA-2:*              matches all messages from device HPA-2

*:Lock               matches messages from all devices which
                   contain "Lock" in the message text

*:*                  matches all messages.
```

If the "rules" file is missing or empty, the software assumes a "*:*" rule. You may have to create a new "rules" file on your, system, there is no default file installed.

4.3.1 Event To Serial Notification

The event to serial notification add-on sends event messages through a serial RS232 interface. This interface may be connected to a separate unit which sends SMS messages or teletype messages from this information.

To use this feature, you need an unused RS232 port at the M&C server. Configuring / installing

this feature is a four step procedure:

1. Create a "rules" file. See page Event Notification Add-Ons for details about this file.
2. Edit the "e2s.properties" file for your needs, some information about the settings in this file are given below.
3. Edit the "vlc.properties" file and set "server.addon=EventToSerial" This line probably is already presented in the file but deactivated by a '#' character in front of it.
4. restart the M&C server

The "e2s.properties" file contains the parameters which configure the behavior of the event to serial notification. The file follows the Java properties file syntax and may contain thefollowing keys / values:

hostName specifies the hostname or IP address of the machine which runs the M&C server. In most cases you will leave this at 'localhost'.

ruleFileName specifies the name of the rule file used by the notification add-on. By default this is 'rules', you may change this if you like to keep multiple rules files which you want to use alternatively.

portName specifies the name of the serial port to use. The default value is '/dev/ttyS0', every serial port available at the machine which is not in use for another purpose may be used.

baudRate specifies the baudrate to be used with the serial port. Default is '9600'.

verbose is for software tests only. For normal operation this always must be 'false'.

The file is read once at system start, hence any changes to this file become effective with the next restart of the M&C server.

4.3.2 Event To Mail Notification

The event to mail notification add-on sends event messages as e-mail notifications to one or more recipients.

To use this feature, the M&C server must be able to reach an SMTP mail server in the network. This may be a private mail server in the company LAN or a public mail server. For the latter case, the M&C server requires internet access.

Configuring / installing this feature is a four step procedure:

1. Create a "rules" file. See page Event Notification Add-Ons for details about this file.
2. Edit the "e2m.properties" file for your needs, some information about the settings in this file are given below.
3. Edit the "vlc.properties" file and set "server.addon=EventToMail" This line probably is already presented in the file but deactivated by a '#' character in front of it.
4. restart the M&C server

The "e2m.properties" file contains the parameters which configure the behavior of the event to mail notification. The file follows the Java properties file syntax and may contain thefollowing

keys / values:

hostName specifies the hostname or IP address of the machine which runs the M&C server. In most cases you will leave this at 'localhost'.

ruleFileName specifies the name of the rule file used by the notification add-on. By default this is 'rules', you may change this if you like to keep multiple rules files which you want to use alternatively.

originate specifies the name or some identification of the M&C system. The text given here will be referenced as the message source in the text body.

minSendInterval specifies the minimal time (minutes) between two messages sent by the notification add-on. For instance, setting this to '60' will configure the software to send mails not more often than once an hour. Events happening in this time will be accumulated and included to the next mail as a list.

summary specifies the position of the message summary in the mail body. It may be one of 'none', 'top' or 'bottom'. If no summary is defined, 'top' is assumed as the default.

smtpHost specifies the name or IP address of the SMTP server which shall be used to send the mails.

smtpPort specifies the port number of the SMTP server which shall be used to send the mails. If not specified, the program assumes port 25 (SMTP).

smtpUser specifies the username to login at the SMTP server. if left empty or commented out, the software uses no SMTP authentication.

smtpPassword specifies the password to login at the SMTP server.

smtpSSL may be one of yes/no. Specifies if SMTPS (SMTP via SSL/TLS) shall be used as message transport. If not specified, the program uses no encryption.

smtpFrom specifies the from address to be set in the messages sent. Please note, the many public SNMP servers require this address to be a valid address because of their spam protection policy.

smtpTo specifies the list of recipients for the mail. Multiple e-mail addresses may be separated by comma characters, they all have to appear in the same line as the 'snmpTo' key.

verbose is for software tests only. For normal operation this always must be 'false'.

The file is read once at system start, hence any changes to this file become effective with the next restart of the M&C server.

4.3.3 Event To Script Notification

The event to script notification add-on calls a user defined script on each event passing the 'rules' filter.

Configuring / installing this feature is a four step procedure:

1. Create a "rules" file. See page Event Notification Add-Ons for details about this file.
2. Edit the "e2c.properties" file for your needs, some information about the settings in this file are given below.
3. Edit the "vlc.properties" file and set "server.addon=EventToScript" This line probably is already presented in the file but deactivated by a '#' character in front of it.
4. restart the M&C server

The "e2c.properties" file contains the parameters which configure the behavior of the event to script notification. The file follows the Java properties file syntax and may contain thefollowing keys / values:

scriptName - specifies the name of the (bash-) script to be executed. The file *must* be located in the ./scripts/ directory of the ***sat-nms*** installation. The file must be set readable and executable for the user that shall execute it.

ruleFileName - specifies the name of the rule file used by the notification add-on. By default this is 'rules', you may change this if you like to keep multiple rules files which you want to use alternatively.

user - if this key is defined, the software does execute the the script with `sudo -u <user> <scriptName> ...` instead of calling the script directly. You probably have to set the password property as well to make this work.

password - specifies the login password of the user set with the 'user' property.

verbose is for software tests only. For normal operation this always must be 'false'.

The file is read once at system start, hence any changes to this file become effective with the next restart of the M&C server.

4.3.4 EDB.properties

Storage depth

Depth defines the number of days the event database records in it's circular storage on disc. Typicall value is 1 year (365 days)

```
depth=365
```

Maximum Report Size

MaxReportSize defines the maximum number of events which are included in a database report. If more events match the search criteria, the reports gets truncated and the operator receives a message about this. This value is just the default used by the client event report window. There you can enter a new one (even greater) for a single request.

```
maxReportSize=1000
```

Event sort order

SortEvents controls if the filtered events are to be sorted by creation time before they are reported to the client. This is necessary in an environment where the events stored in another order than they were created (e.g. in the NMS or if multiple MNC systems using the same event database).

Therefore sortEvents is assumed to `true` if not stated otherwise. In a MNC environment reporting a large number of events can be speed up significantly by settings this to `false`

```
sortEvents=false
## sortEvents=true
```

Event DB debugging

Set to `true` for activation of additional debug output. It is disabled by default `false` and should be not enabled in production environments.

```
```

4.4 Remote Control

The satnms M&C software support several remote control interface which let an superordinate NMS control the M&C. In this section the direct remote interfaces of the M&C server are discussed. Both require direct IP access to the M&C server, accepting any possible security riscs arising from that.

The preferred method of monitoring or controlling an M&C from an external program is the HTTPS based API of the M&C backend. USing this, all M&C systems controlled by the backend may be monitored thru one single interface.

The direct remote interfaces of the M&C server areSNMP and a text based terminal protocol using TCP/SSL Ports for remote contol.

The SNMP Agent built into the M&C server comes in two different flavors: One is table based and standardized, offers a limited number of parameters in a MIB which is the same for all satnms M&C systems. The second one is application specific, for every satnms M&C installation a unique MIB can be generated which contains exactly the parameter which shal be monitored or controlled.

4.4.1 SNMP Control

The sat-nms software contains two SNMP agents which may be used to control the software from an external NMS.

Universal SNMP Agent

The universal SNMP agent publishes a limited number of device parameters in a fixed, table oriented MIB. This SNMP agent permits to monitor and partially control any sat-nms M&C using

the same MIB - regardless of the device configuration of the particular M&C. The universal SNMP agent listens at port 2261, it is based on SNMPv2.

The MIB provides one table which contains all devices which are configured in the sat-nms M&C. No special mapping is necessary for this table as there are only very common parameters like the device name, its fault state or its administrative state in this table.

Beside this, the MIB contains a couple of tables, each representing all devices belonging to a so called 'device class'. For instance, there is one table containing all HPAs in the M&C and one table containing all waveguide switches. These class specific tables contain some parameters which are common to the devices of the particular class. The HPA table contains parameters for tx-on, for attenuation and forthe measured output power for each device, the waveguide switch table provides a parameter for the switch position.

As device drivers sometimes use different parameter names for the same or similar function, an individual mapping from the 'universal' parameter in the MIB to the real parameter in the device is necessary for every single sat-nms device driver. Device drivers which do not contain any information about the device class this devices belongs to and how the parameters are to be mapped into the MIB only appear in the in the general device table of the MIB.

A sat-nms device (physical or logical) may be represented by multiple device classes in the MIB or by multiple instances of the same class. For example a combined upconverter and HPA may appera as a HPA in this table (with its HPA specific parameters) and a second time in the upconverter table with its frequency parameter.

Also devices consisting of multiple modules can be treated this way in the MIB, there are quad block upconverter on the market which provide four independent converter modules in one device. Such a device can be mapped in way, that it appears as four BUC devices in that table.

By default the universal SNMP agent is disabled. Use the following keys in the vlc.properties file to enable the agent, set the read/write community strings and an optional list of trap/notification destinations. Each IP address in this list will receive a notification message for each device which changes its fault state. Example:

```
snmp.agent.enable=yes
snmp.agent.readCommunity=public
snmp.agent.writeCommunity=private
snmp.agent.trapTargets=192.168.0.89:2162 127.0.0.1:162
```

'snmp.agent.trapTargets' defines a list of zero or more IP addresses in dotted quad notation. The addresses may contain a port number like in the example above, if no port number is specified, the standard SNMP trap port 162 is assumed. There is no fixed limitation in in the software for the number of trap destinations, you should however be aware, that a large number of destinations (greater than 10) may cause performance problems, depending on network speed and response time of the targets.

The agent sends a SNMPv2 notification (mncDeviceFaultChanged from the MIB) every time the fault state of a device changes. The notification message has the name of the device which

caused the notification and its new fault state as varbinds attached. At program start, one initial notification message for each device is sent.

Application Specific SNMP Agent

The application specific agent provided by the sat-nms software is based on SNMPv1, it accepts requests at UDP port 2161. It permits read and write access from the 'public' community. Beside that, the sat-nms M&C may be configured to send SNMP traps on changes of certain parameters, e.g. fault flags.

Each M&C system is configured individually for the device setup it controls. Therefore also the SNMP agent configuration and the specific MIB for a M&C must be unique for each installed system. With the sat-nms M&C / VLC, the SNMP agent gets configured by a (text based) configuration file which defines the M&C parameters which shall be visible through SNMP.

The typical procedure to prepare the sat-nms M&C for SNMP access is as follows:

1. Create a template SNMP configuration file using the 'create-snmp.template' utility program. This template file contains all parameters available in this particular M&C installation.
2. From this template file edit the SNMP configuration setup or simply copy the template to the configuration file if you want to export all parameters via SNMP.
3. Restart the M&C server to make it read the SNMP configuration file.
4. Invoke the 'create-satnms.mib' utility program to create a MIB definition file reflecting the actual setup.

4.4.1.1 SNMP Parameter Translations

SNMP treats parameters (objects) in a different way as the sat-nms software does. The SNMP agent translates the internal representation of M&C parameters to the SNMP representation and vice versa. The default translation rules are listed in the table below:

Default Translation

- sat-nms *data type* --- *SNMP data type**comment*
- INTEGER --- INTEGER : No translation necessary.
- FLOAT --- INTEGERSNMPv1 : cannot handle floating point numbers. FLOAT variables therefore are translated to integer values when exported as a SNMP object. The value is scaled by 10^ *n* where *n* is the number of precision digits set for this variable in the device driver definition file. Example: The azimuth value of an antenna controller appears with three precision digits as 180.000 in the sat-nms user interface. The SNMP representation of this angle will be 180000 (floating point value multiplied by 10^3). When the SNMP agent receives values to set at the M&C, the translation happens the other way round.
- TEXT --- OCTET-STRING : Text type variables translate as OCTET-STRING SNMP objects. In the MIB, text variables should be declared as 'DisplayString' (defined in RFC1213-MIB). This ensures, that the strings are shown as expected by the MIB browser. (Some browsers assume OCTET-STRINGs to be binary and display a hex-dump instead of the textual contents.)

- CHOICE --- INTEGER : Internally the sat-nms software treats CHOICE parameters as text. SNMP uses enumerated integers for this. The value of a sat-nms CHOICE parameter translates to the position of the value in the list of choices as defined in device driver file. If - for some reason - the value does not match any of the selections given by the device driver, it translates to 0. The MIB should define memnotics for all selections.
- BOOLEAN --- INTEGER : A boolean value translates to an enumerated integer with the values 0=FALSE and 1=TRUE.

The SNMP agent knows from the sat-nms variable definition if a parameter may be accessed read-write or read-only. Each individual parameter may be limited to read-only access when exported to SNMP (see below).

'force to text' Translation

The SNMP agent may be configured (individually for each parameter) to force a text-translation to OCTET-STRING, regardless of the type of the parameter. In this case, INTEGER or FLOAT values translate to a readable text, formatted with the precision defined in the device driver file and the unit string appended. BOOLEAN value translate to the keywords TRUE or FALSE and any other parameter translate the text the sat-nms user interface shows. The MIB should contain a 'DisplayString' entry for each parameter which is configured this way. If the agent receives a SET request for a parameter which ist translated in 'force to text' mode, it parses the text and sets the value as the user interface would do.

The 'force to text' option specially is valuable together with the 'force to readonly' option described below. It provides a simple method to create easy to read status reports which can be displayed in a MIB browser.

'force to readonly' Translation

The 'force to readonly' option permits to limit the access to read-only for each individual parameter. This may be used to prevent SNMP users from changing sensible settings in the M&C.

'suppress range limits' Translation

The 'suppress range limits' option suppresses the output of the min/max range of a numeric parameter. This may be useful if this range dynamically changes and shall not be fixed to the limits valid at the time when the MIB is created.

Limitations

Not all M&C parameters may be translated to SNMP objects in a way that makes sense. First of all, there are a couple of M&C variables which carry complex information, binary coded as Java objects. Translating these objects to SNMP is not possible as the information contained in these objects is for internal use in the sat-nms software only.

Another problem of translating values between their sat-nms representation and SNMP objects arises if the M&C dynamically changes the definition of this variable during runtime. This is a special feature of the sat-nms software which makes it's internal message concept superior to SNMP for this application.

Example: A satellite modem is capable to encode with FEC rates 1/2, 3/4 and 7/8 with BPSK modulation. If switched to QPSK, also the rates 4/5 and 5/6 are available. The device driver will change the definition of the 'fec' parameter as the 'modulation-type' parameter changes.

It is easy to understand that the translation of the 'fec' along the enumeration list given in the device driver will give wrong results after the device driver changed the parameter definition. It is strongly recommended to configure such parameter as 'force to text' and 'force to readonly'. This way at least a correct display via SNMP can be achieved.

A similar situation arises if a device dynamically changes the limits for a numeric parameter. An example for this are the pointing angles of an antenna: The soft limits set by the operator will be used as range limits for this parameter. If they are changed after the MIB has been created, they will no longer match the limits stated in the mib. Such parameters should be marked with the 'suppress range limits' translation option in the configuration file.

4.4.1.2 Configuring the SNMP Agent

The application specific SNMP agent gets configured by a the file 'snmp.setup'. If this file exists in the VLC's home directory while the M&C server starts, the SNMP agent is started. The sat-nms software contains a utility program called 'create-snmp.template' to create a template of this file including all parameters of a particular M&C / VLC. The file is a text file using the following format:

- Empty lines and lines starting with '#' are ignored.
- At the beginning of the file, the global settings 'systemname', 'systemid' and 'traphost' must be defined (see example below).
- After this file header, each line must contain exactly one sat-nms parameter identifier, consisting of the device name followed by a dot and the variable identifier.
- Each parameter identifier may be followed by zero or more parameter attributes, separated by space characters.

Global settings

The file 'snmp.setup' must define the global settings 'systemname', 'systemid' and 'traphost' before the first parameter identifier appears in the file. The order of appearance does not matter.

- **traphost<aaa.bbb.ccc.ddd>** --- Defines the IP address of the host which shall receive any traps from this M&C. Traps always are sent to the standard port number 162.
- **systemid <n>** --- Defines the base node number of the MIB tree created for this M&C. The created MIB tree is a branch of *iso.org.dod.internet.private.enterprises.satservice* , the 'systemid' parameter defines the number of the child node below *satservice* . Numbers 1 .. 99 are reserved for special applications. The 'create-snmp.template' utility program uses the M&C serial number as a default for this parameter to ensure a unique value for each M&C.
- **systemname <name>** --- Defines the memnotics for the 'systemid' parameter described above. Following the conventions for MIB definition, this should be a single word, starting with a letter and consisting entirely of letters and digits. The 'create-

snmp.template' utility program prepends 'vlc' to the serial number in order to create a unique value for this parameter.

Parameter attributes

The software accepts the following parameter attribute keywords following a parameter identifier. The activate the corresponding translation option for this parameter.

- **RO** --- Forces this parameter to be treated as read-only, even if it has read-write access within the sat-nms environment. It is not necessary to mark parameters with **RO** if they already are marked as read-only by the sat-nms device driver.
- **TEXT** --- Forces this parameter to be translated into a readable text (OCTET-STRING) when exported to the SNMP world, regardless of it's native data type. See chapter SNMP Parameter Translations for more information about the software converts native data types to SNMP types an vice versa.
- **NORANGE** --- Suppresses the output of a mi/max range for numeric parameters. This is useful for parameter which dynamically change their limits. See chapter SNMP Parameter Translations for more information about the software converts native data types to SNMP types an vice versa.
- **TRAP** --- Tells the software to send an SNMP trap if this parameter changes. Although mostly used for fault flags, this feature is not limited to this application. Any M&C parameter may be monitored by sending TRAPS.

MIB tree creation

When reading the 'snmp.setup' file, the software dynamically allocates MIB nodes for each parameter. The program splits up parameter identifiers at the dots and builds a MIB tree breaking down the M&C parameter structure along devices and subsystems. Node numbers are assigned automatically starting at 1, parent nodes are created as needed. This means, the order of the parameters in the 'snmp.setup' file determines the numbering of OIDs.

As a consequence of the automatic MIB tree creation, existing MIBs usually become invalid after a configuration change in a M&C, due to the renumbering of the OIDs.

However, with the knowledge about the OID assignment algorithm used by the software, minor configuration changes can be worked into the SNMP configuration while keeping the existing OID numbering unchanged. There are simply two rules to follow:

1. Do not remove existing definitions. Neither single parameters nor complete devices. Deleting definitions would cause a renumbering (decrement) of the following nodes.
2. Add additional parameter definitions always at the very end of the 'snmp.setup' file. Although for human readers the order of parameters in the file will look somewhat 'messy', the software will assign the OIDs in a way that the numbering of existing parameters will not change.

If you follow the rules above, you still can use the previous MIB of a M&C after an extension of the configuration. You however will not be able to access the added parameters as long you use the old MIB.

'snmp.setup' Example

The example below shows the contents of a short 'snmp.setup' file.

```
### snmp.setup example
### created on Thu Jun 22 19:11:18 GMT 2006

traphost 127.0.0.1
systemname vlc2345
systemid 2345

SUMMARY.fault                TRAP
E1.fault                   TRAP
E1.mode                     RO
SW.fault                   TRAP
SW.mode                     RO
```

Fault messages

If the software encounters problems while it reads the 'snmp.setup' file, it issues fault messages to the sat-nms event log. Hence, after a change of the SNMP configuration, you should inspect the event log after the server restart. The following error messages are possible:

Unknown variable in line n of 'snmp.setup': The snmp.setup file references a sat-nms variable which does not exist. The reason may be a misspelled parameter name or you changed the sat-nms device setup without adapting the SNMP configuration.

Unknown attribute ABC in line n of 'snmp.setup': You specified a parameter attribute which is neither 'TRAP', 'TEXT' nor 'RO'.

Warning: 'snmp.setup' has 0 entries: There is a 'snmp.setup' file, but it does not specify any parameters

Failed to read 'snmp.setup': A general error occurred. Delete and recreate 'snmp.setup'.

4.4.1.3 The 'create-snmp.template' Utility Program

To assist you in setting up the SNMP configuration file, the sat-nms software comes with a utility program called 'create-snmp.template'. This program creates a template configuration file which contains all (or the most common) M&C parameters of the actual system.

To create a template configuration file, perform the following steps:

1. Open a telnet window to the M&C server
2. Log in as user 'satnms', password 'satnms'.
3. Type 'create-snmp.template <ENTER>' to invoke the program

This creates a file called 'snmp.template', a template for the 'snmp.setup' file. It defines all M&C parameters of the system except of the device setup variables to be accessible via SNMP.

The M&C variables appear in alphabetical order, all fault flags are marked to send SNMP traps in case of a change of the value. To use the template file, rename it to 'snmp.setup' and restart the software. To make certain parameters invisible for the SNMP NMS, remove the corresponding lines from the file or put comment characters ('#') in front of them.

The 'create-snmp.template' utility program accepts a number of command line options which let you modify the default behavior of the program. These options are:

- **--include-config** --- Includes the device setup variables into the template file. Normally the program skips these variables.
- **--view-only** --- Forces all parameter to be read-only and translated to text (parameter attributes 'TEXT RO'). This is a fail safe mode, making it impossible for the SNMP user to change anything at the M&C system.
- **--comment** --- This option places a comment character in front of line of the file. This is valuable if you intend to export only a small number of parameters to the SNMP world. By default all parameters are disabled, you may enable the SNMP export of particular parameter by removing the comment character in front ot the parameter name.

For example, typing 'create-snmp.template --include-config --comment <ENTER>' in the telnet window creates a template file which also includes the device setup variables, but with all parameter definitions commented out.

4.4.1.4 The 'create-satnms.mib' Utility Program

Once the SNMP agent of the VLC / M&C has been configured and the server has been restarted, the agent is active and listens on UDP port 2161 for SNMP requests. At this point, calling the 'create-satnms.mib' utility program causes the server to write a MIB file which exactly matches the agent's internal MIB.

Using the the 'create-satnms.mib' utility program is as follows:

1. Open a telnet window to the M&C server
2. Log in as user 'satnms', password 'satnms'.
3. Type 'create-satnms.mib <ENTER>' to invoke the program

This creates the MIB file (file name 'satnms.mib') in the server's home directory. The file also appears in the 'public' share as a symbolic link, making it readable to other computers in the network.

4.4.2 TCP/SSL Remote Control

sat-nms M&C systems can be controlled remotely using a simple text based IP protocol. A remote application may use this protocol to query state information or device settings and to control the settings of each individual device. The M&C provides three flavours of this protocol on three different IP ports:

- Port 2015 accepts SSL connections giving monitor and control access to all parameters / devices in the M&C
- Port 2016 accepts plain TCP connections giving monitor and control access to all

parameters / devices in the M&C
- Port 2017 accepts plain TCP connections like port 2016, but grants monitoring access only.

All three ports are disabled by default. In order to use them, they have to be enabled in the vlc.properties file:

```
server.rcontrol.ssl.read-write=yes
server.rcontrol.tcp.read-write=yes
server.rcontrol.tcp.read-only=yes
```

To make changes in the vlc.properties file effective, you must restart the M&C server. The protocol itself is very simple, there are only three commands:

```
? *parameter-id*
```

Queries the actual state of a parameter.*parameter-id* is a textual string as used in the configuration of logical devices, e.g. BCRX-1.power identifies the power reading of a SatService beacon receiver named BCRX-1. The parameter may be any device setting or a status reading. If there is a value known for the given parameter-id, the parameter-id followed by a space character and the actual value is replied, numeric values are formatted in the same way as for presenting them at the sat-nms GUI. If the parameter-id is not known or if the device driver could read a value from the device since start of the program, nothing is replied.

```
@ *parameter-id*
```

Subscribes for updates on every change of a parameter. If there is a value known for the given parameter-id, the parameter-id followed by a space character and the actual value is replied, numeric values are formatted in the same way as for presenting them at the sat-nms GUI. If the parameter-id is not known or if the device driver could read a value from the device since start of the program, nothing is replied. Every time the value of this parameter changes, the M&C will send a line with the parameter-id followed by a space character and the actual value of the parameter.

```
! *parameter-id new-value*
```

Sets a parameter to the given value. *new-value* is parsed as if entered to a field in the sat-nms GUI. There is no reply to this command. If you want to check if the new value has been accepted, use the '?' or '@' commands. At the monitoring only port 2017 set commands are silently ignored.

Remarks

- Subscriptions remain active until the connection is closed, there is no 'unsubscribe' command.
- If you are using subscriptions, it is always possible that you receive a change message for a changed parameter before you receive the expected reply to a subscribe or query

command. You always must be capable to receive messages in any sequence.

5 Installation

This section of the manual provides installation instruction for the different modules of the ***sat-nms*** Monitoring & Control software.

> ***Remark:*** On a preconfigured system delivered by SatService these step as usually **not** required. So this manual is aimed especially at people who want to deploy the system in virtual machines or customer provided bare metal server or for deployments in private cloud environment. And it is intended for a better understanding of your installation.

Quick access links to the main sections of the document:

- Base Debian Linux setup
  - packages: satnms4-base, satnms4-utils
- MNC service
  - packages: satnms4-mnc, satnms4-images, satnms4-documentation, satnms4-jars
- EventDB service
  - packages: satnms4-mnc, satnms4-images, satnms4-documentation, satnms4-jars
- Backend service
  - packages: satnms4-backend
- WebClient and nginx
  - packages: satnms4-webclient, satnms4-images, satnms4-documentation
- Database SatDB
  - packages: satnms4-satdb

There are different way where to installed all these components. The simplest solution is to install all components on one host (bare metal server or virtual machine). On the other hand all components can be run on different hosts for several reasons like redundancy or load distribution.

Please refer to the chapter Architecture for the different options. TODO!!!

The following chapters consider all components as a stand-alone installation. Therefore some steps may be repeated and can be skipped in different scenarios. But the installation of all services (MNC, backend, EventDB, WebClient and SatDB) expect the base Debian Linux installation. So whatever you want to install, make sure you followed first the instruction in the chapter Base Debian Linux setup

5.1 Installation Base Debian Linux

This section provides installation instructions for the ***sat-nms*** base and utils packages for the ***sat-nms*** Monitoring & Control System.

These packages are used to add settings and tools to a standard minimal Debian 12 installation. The following chapter descripes the installation on Debian Linux 12 but should be similar for other Debian-based distributions.

5.1.1 Requirements

- Minimal Debian 12 Installation and console or SSH access
- headless installation is sufficient
- root permission in Linux either via `su` or `sudo`
  - all examples in this manual assume that you get root shell with the `su` command
  - for installation with no direct `root` login, you have to add `sudo` in front of all commands which requires `root` permission
- access to Debian 12 repositories either via Internet or from a local Debian archive mirror
  - check with `apt-get update` access to the configured repository is available.
- for base setup: `satnms4-base_[version].deb` package (in the following referred to as `satnms4-base`)
- for utilities setup: `satnms4-utils_[version].deb` package (in the following referred to as `satnms4-utils`)

5.1.2 For the impatient

This section provides a quick installation guide for the impatient and experienced Debian Linux users. Detailed information are in the following chapters.

Install Debian Linux 12 on your host with your favorite installation method.

We recommend the following settings:

- Language: `English`
- Disk: 20.0 GB, ext4 filesystem
- TaskSel: not a full installation, just select
  - SSH Server
  - Standard system utilities
- Time: `UTC`
- Default user: `satnms`

Install ***sat-nms*** base components

```
apt-get update
apt-get upgrade
apt install /home/public/satnms4-base_[version].deb
apt install /home/public/satnms4-utils_[version].deb
reboot
```

5.1.3 Installation

For the following instructions we assume that you are using Debian 12. Similar Linux distributions like Ubuntu may also work but are not covered by this manual.

Debian Linux 12

Please follow the standard Debian 12 instruction for a minimal Debian installation. We

recommend the following setting for the Debian installer:

- Language: `English`
- locale: `en_GB.UTF-8`
- Network: fixed IP address
- Clock: use NTP
- Root user: set password and allow login
- Normal user: `satnms`
- Timezone: `UTC`
- Disk: 20GB partion for all with ext4
- TaskSel: only `SSH Server` and `Standard system utilities`

Additional packages

For convenience we recommend the following additional packages:

- curl
- debsums
- dialog
- htop
- mc
- rsync
- snmp
- sudo
- tcpdump
- tnftp
- vim

```
root@satnms7-dev:~# apt-get install curl debsums dialog htop mc rsync snmp sudo tcpdump
```

satnms4-base package

The `satnms4-base` package contains files and directories required by the other satnms4 components. It should be installed on each host which run ***sat-nms*** MNC components.

```
root@satnms7-dev:~# apt-get install ./satnms4-base_1.2.2-1_all.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'satnms4-base' instead of './satnms4-base_1.2.2-1_all.deb'
The following NEW packages will be installed:
  satnms4-base
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.
Need to get 0 B/462 kB of archives.
After this operation, 0 B of additional disk space will be used.
Get:1 /root/satnms4-base_1.2.2-1_all.deb satnms4-base all 1.2.2-1 [462 kB]
Selecting previously unselected package satnms4-base.
(Reading database ... 36810 files and directories currently installed.)
Preparing to unpack .../satnms4-base_1.2.2-1_all.deb ...
Unpacking satnms4-base (1.2.2-1) ...
Setting up satnms4-base (1.2.2-1) ...
Created symlink /etc/systemd/system/multi-user.target.wants/satnms.service → /etc/systemd/
Processing triggers for mailcap (3.70+nmu1) ...
```

Beside installing different files it will also setup the following:

- create a user `satnms` if not already exists
- create a directory `/home/public` which should be used later to place satnms4 packages and backups
- enable `sudo` for a list of commands
- add additional MOTD (message of the day) scripts to show information on login
- and some more

  Remark: All satnms4 packages must be installed from local source. All following instructions assume that you have these packages in the folder `/home/public` on the host where you want to install them.

If the user `satnms` does not exists before installing this package, a new user will be created. This user will be used to run the different ***sat-nms*** services. So it is required. By default it is not possible to login to this user, because there is no password set. Login as `root` and change the password for the user `satnms`:

```
root@satnms7-dev:~# passwd satnms
New password:
Retype new password:
passwd: password updated successfully
```

satnms4-utils package

The `satnms4-utils` package contains a collection of utilities for the***sat-nms*** Monitoring & Control System like backup and restore scripts.

```
root@satnms7-dev:/home/public# apt install ./satnms4-utils_1.0.6-1_all.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'satnms4-utils' instead of './satnms4-utils_1.0.6-1_all.deb'
The following NEW packages will be installed:
  satnms4-utils
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.
Need to get 0 B/30.7 kB of archives.
After this operation, 0 B of additional disk space will be used.
Get:1 /home/public/satnms4-utils_1.0.6-1_all.deb satnms4-utils all 1.0.6-1 [30.7 kB]
Selecting previously unselected package satnms4-utils.
(Reading database ... 36932 files and directories currently installed.)
Preparing to unpack .../satnms4-utils_1.0.6-1_all.deb ...
Unpacking satnms4-utils (1.0.6-1) ...
Setting up satnms4-utils (1.0.6-1) ...
Processing triggers for mailcap (3.70+nmu1) ...
```

Common Linux settings

In preinstalled systems delivered by SatService a dedicated file will display the version of the ***sat-nms*** Linux Operation System installation: `/etc/satnms_version` .

Its format is defined as: `[linux-distribution]-satnms-[version] [date]` . For customer build OS version it is required to create this file by your own.

- `linux-distribution` is usually `debian` , but other names are allowed like `ubuntu`
- the second word needs to be `-satnms-`
  - required because several tools parsing this file to get the OS version
  - the Sysinfo device uses this information to display the matching server information
- version format is `[major-version].[minor-version][suffix] [date]` e.g. `7.01`
  - major-number must be 7
  - minor-number will be increased if SatService creates new OS images
  - for customer builds minor numbers needs to be managed by customer
  - optional suffix can be added to mark special editions: e.g. `7.01idu` shows that it is a special OS image for the ***sat-nms*** ACU Indoor Unit
  - the date should be in format `YYYY-MM-DD`

```
satnms@satnms7-dev:~$ cat /etc/satnms_version
debian-satnms-7.01 2023-10-05
```

The follwing additional settings are recommended for convenience.

- `/home/satnms/.bashrc` : uncomment line `force_color_prompt=yes` to enable colored prompt
- `/root/.bashrc` : configure prompt colors, add the following line:

```
PS1='${debian_chroot:+($debian_chroot)}\[\033[01;31m\]\u@\[\033[01;33m\]\h\[\033[00m\]:
```

5.2 Installation MNC Service

This section provides installation instructions for the MNC service used by the***sat-nms*** Monitoring & Control System.

The MNC service runs device drivers and logical device and is the interface to the equipment to be monitored and controlled.

The following topics will be covered by the Administration Manual

- Update ***sat-nms*** MNC service TODO LINK !!!
- Backup and restore ***sat-nms*** MNC service settings TODO LINK !!!

5.2.1 Requirements

- Base Debian 12 Installation with installed packages
  - `satnms4-base`
  - `satnms4-utils`
- console or SSH access
- headless installation is sufficient
- root permission in Linux either via `su` or `sudo`
  - all examples in this manual assume that you get root shell with the `su` command
  - for installation with no direct `root` login, you have to add `sudo` in front of all commands which requires `root` permission
- for MNC installation the following packages:
  - `satnms4-documentation_[version].deb` package (in the following referred to as `satnms4-documentation`)
  - `satnms4-images_[version].deb` package (in the following referred to as `satnms4-images`)
  - `satnms4-jars_[version].deb` package (in the following referred to as `satnms4-jars`)
  - `satnms4-mnc_[version].deb` package (in the following referred to as `satnms4-mnc`)

5.2.2 For the impatient

This section provides a quick installation guide for the impatient and experienced Debian Linux users. Detailed information are in the following chapters.

```
apt-get update
apt-get upgrade
apt-get install openjdk-17-jre-headless
apt install /home/public/satnms4-documentation_[version].deb
apt install /home/public/satnms4-images_[version].deb
apt install /home/public/satnms4-jars_[version].deb
apt install /home/public/satnms4-mnc_[version].deb
systemctl enable satnms
systemctl start satnms
```

5.2.3 Installation

One external tools must be installed:

1. OpenJDK Java Runtime Environment (JRE)
2. JQ Pretty print of JSON data on CLI (optional)

Debian provided installation packages (`.deb`) for OpenJDK 17.

- login as `root`
- update all installed Debian packages: `apt-get update; apt-get upgrade`
- install JRE from Debian repository: `apt-get install openjdk-17-jre-headless`

example output

```
satnms@satnms7-dev:~$ su -
Password:
root@satnms7-dev:~# apt-get install openjdk-17-jre-headless
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following additional packages will be installed:
  ... ca-certificates-java java-common ...
Suggested packages:
  ...
The following NEW packages will be installed:
  ... ca-certificates-java java-common openjdk-17-jre-headless ...
0 upgraded, 21 newly installed, 0 to remove and 1 not upgraded.
Need to get 50.3 MB of archives.
After this operation, 210 MB of additional disk space will be used.
Do you want to continue? [Y/n] y
... downloading and installing packages ...
```

To test if Java Runtime was installed successfully, run `java -version` as user `satnms` :

example output

```
satnms@satnms7-dev:/home/public$ java -version
openjdk version "17.0.14" 2025-01-21
OpenJDK Runtime Environment (build 17.0.14+7-Debian-1deb12u1)
OpenJDK 64-Bit Server VM (build 17.0.14+7-Debian-1deb12u1, mixed mode, sharing)
```

Now install the ***sat-nms*** backend software package:

- upload `satnms4-documentation` , `satnms4-images` , `satnms4-jars` and `satnms4-mnc` package to `/home/public on the target system
- login as `root`
- install the local satnms4-* packages
  - `apt install /home/public/satnms4-documentation_[version].deb`
  - `apt install /home/public/satnms4-images_[version].deb`
  - `apt install /home/public/satnms4-jars_[version].deb`
  - `apt install /home/public/satnms4-mnc_[version].deb`

example output for package satnms4-mnc

```
root@satnms7-dev:/home/public# apt-get install ./satnms4-mnc_3.68.9-1_all.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'satnms4-mnc' instead of './satnms4-mnc_3.68.9-1_all.deb'
The following packages will be upgraded:
  satnms4-mnc
1 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
Need to get 0 B/10.2 MB of archives.
After this operation, 0 B of additional disk space will be used.
Get:1 /home/public/satnms4-mnc_3.68.9-1_all.deb satnms4-mnc all 3.68.9-1 [10.2 MB]
Reading changelogs... Done
(Reading database ... 48696 files and directories currently installed.)
Preparing to unpack .../satnms4-mnc_3.68.9-1_all.deb ...
Unpacking satnms4-mnc (3.68.9-1) over (3.68.2-1) ...
Setting up satnms4-mnc (3.68.9-1) ...
```

On success you will find a multiple new files and directories `/home/satnms/` like `satnms.jar` and directories `drivers` , `protocols` etc.

5.2.4 Configuration

This section describes only the intital configuration step for the***sat-nms*** MNC service. Because the configuration of the M&C itself can be done via Web interface. Please refere to the following chapters:

- web client: Device-Setup
- web client: Screen-Editor

The system ships a default configuration which is "ready-to-run" but you can modify some configuration to adapt the system to your environment. For a all-in-one MNC System no additional configuration is required.

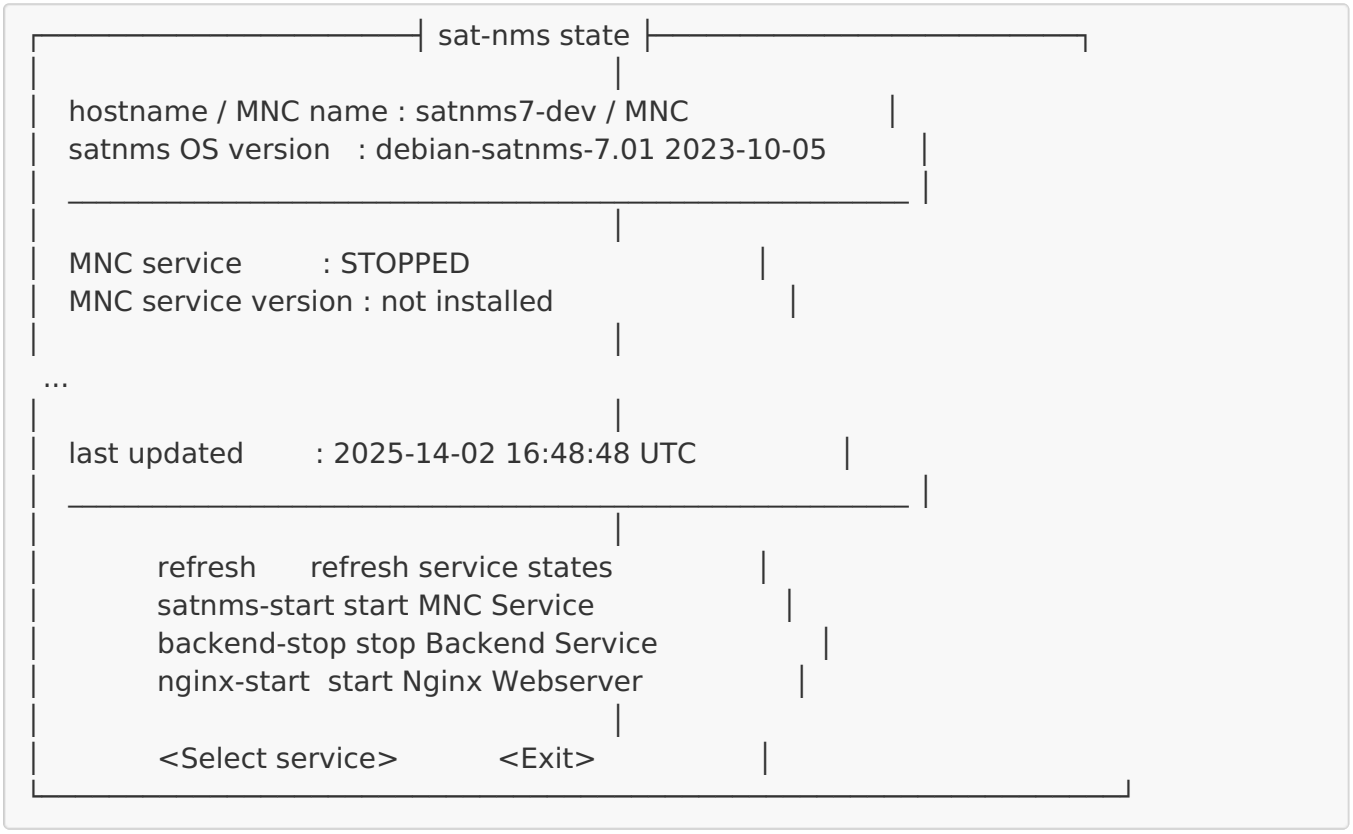
Several other options require your attention only for complex setups which includes server redundancy. A detailed description of all options from is available in the Administration Section of this Manual.

To ensure the MNC service will automatically start on reboot, login as root and enable this service.

- login as `root`
- enable autostart with `systemctl enable satnms"

Now you can start the backend service as user `satnms` and check if its running.

- login as `satnms`
- run the `satnms-watch`



The output depends on the installed services. In the example above, only the ***sat-nms*** MNC service is installed and running.

You can also control the MNC service directly with the follwing commands:

- start MNC service `sudo systemctl start satnms`
- stop MNC service `sudo systemctl stop satnms`

Check if the MNC service start successfully:

- status of MNC service `systemctl status satnms`

```
satnms@satnms7-dev:~/backend$ systemctl status backend
TODO
```

You can test if the MNC started successfully by checking the output of the log file `/home/satnms/debug.log` . The first line shows an early stage of start process and is an indication that the MNC service begins to start. The second line shows that all sub processes are now initialized and the MNC service is ready to serve client requests. Starting from this the backend service or clients are able to connect to the MNC service.

```
satnms@satnms7-dev:~$ tail /home/satnms/debug.log
...
000000 2025-03-05 12:32:18 2025-03-05 12:32:18   I SYSTEM Loading setup data (sat-nms MI
...
000000 2025-03-05 12:32:18 2025-03-05 12:32:18   I SYSTEM VLC 3.68.9 2025-03-05 07:22:0
...
```

Some more details and extended error messages if something failed are available in `/home/satnms/.panic.log`

A typical output of the default installation should looks like this:

```
satnms@satnms:~$ cat .panic.log
satnms version 3.68.9 2025-03-05 07:22:02
TRAPREC: File traprcv.json not found
TRAPREC: Cannot parse traprcv.json
TRAPREC: Trap receiver not started.
Universal SNMP agent listening at port 2261
TCP remote control server (r/w) listening at port 2016
TCP remote control server (r/o) listening at port 2017
SSL remote control server (r/w) listening at port 2015
```

A detailed description how to run the ***sat-nms*** MNC service is available in the administration manual.

Troubleshooting

If you have trouble to bring up the MNC service check first if the MNC service is still running with:

- `systemctl status satnms` or
- `/home/satnms/satnms-stat`

Additionally you can lookup the process ID (PID) of the backend service process:

```
satnms@satnms7-dev:~$  ps aux |grep satnms.jar
satnms   8204 ?   Sl   25:18 java -cp satnms.jar:/home/satnms/jars/* -mx512m -Djava.security.
```

Now check if the MNC process with this PID (here 8204 from the second column) is associated to a process listening on TCP ports from 2000 and above. The real number of listing ports depends on the actual configuration, but at least 2000-2007 should be visible.

```
satnms@satnms7-dev:~$ ss -tanp |grep 8204
LISTEN 0      50                 *:2000             *:*    users:(("java",pid=8204,fd=11))
LISTEN 0      50                 *:2001             *:*    users:(("java",pid=8204,fd=35))
LISTEN 0      50                 *:2002             *:*    users:(("java",pid=8204,fd=42))
LISTEN 0      50                 *:2003             *:*    users:(("java",pid=8204,fd=40))
LISTEN 0      50                 *:2004             *:*    users:(("java",pid=8204,fd=12))
LISTEN 0      50                 *:2005             *:*    users:(("java",pid=8204,fd=13))
LISTEN 0      50                 *:2006             *:*    users:(("java",pid=8204,fd=19))
LISTEN 0      50                 *:2007             *:*    users:(("java",pid=8204,fd=17))
...
```

!!!! The backend internal web server runs on Port 8443 and serves only HTTPS requests. ???? You should that this process is `LISTEN` on all interfaces (`*:8443`)

5.3 Installation Backend Service

This section provides installation instructions for the backend service used by the***sat-nms*** Monitoring & Control System.

The backend provides an unified REST-API to control all parts of an sat-nms Monitoring & Control System. It is used by the sat-nms WebClient but also available for third party applications. Please refere to the [API documentation](API Reference) for details.

The following topics will be covered by the Administration Manual

- Update ***sat-nms*** backend TODO LINK !!!
- Backup and restore ***sat-nms*** backend settings TODO LINK !!!

5.3.1 Requirements

- Base Debian 12 Installation with installed packages
  - `satnms4-base`
  - `satnms4-utils`
- console or SSH access
- headless installation is sufficient
- root permission in Linux either via `su` or `sudo`
  - all examples in this manual assume that you get root shell with the `su` command
  - for installation with no direct `root` login, you have to add `sudo` in front of all commands which requires `root` permission

- for backend installation: `satnms4-backend_[version].deb` package (in the following referred to as `satnms4-backend`)

5.3.2 For the impatient

This section provides a quick installation guide for the impatient and experienced Debian Linux users. Detailed information are in the following chapters.

```
apt-get update
apt-get upgrade
apt-get install openjdk-17-jre-headless
apt install /home/public/satnms4-backend_[version].deb
cp /home/satnms/backend/backend.properties.default /home/satnms/backend/backend.proper
systemctl enable backend
systemctl start backend
```

5.3.3 Installation

One external tools must be installed:

1. OpenJDK Java Runtime Environment (JRE)
2. JQ Pretty print of JSON data on CLI (optional)

Debian provided installation packages (`.deb`) for OpenJDK 17.

- login as `root`
- update all installed Debian packages: `apt-get update; apt-get upgrade`
- install JRE from Debian repository: `apt-get install openjdk-17-jre-headless`

example output

```
satnms@satnms7-dev:~$ su -
Password:
root@satnms7-dev:~# apt-get install openjdk-17-jre-headless
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following additional packages will be installed:
  ... ca-certificates-java java-common ...
Suggested packages:
  ...
The following NEW packages will be installed:
  ... ca-certificates-java java-common openjdk-17-jre-headless ...
0 upgraded, 21 newly installed, 0 to remove and 1 not upgraded.
Need to get 50.3 MB of archives.
After this operation, 210 MB of additional disk space will be used.
Do you want to continue? [Y/n] y
... downloading and installing packages ...
```

To test if Java Runtime was installed successfully, run `java -version` as user `satnms` :

example output

```
satnms@satnms7-dev:/home/public$ java -version
openjdk version "17.0.14" 2025-01-21
OpenJDK Runtime Environment (build 17.0.14+7-Debian-1deb12u1)
OpenJDK 64-Bit Server VM (build 17.0.14+7-Debian-1deb12u1, mixed mode, sharing)
```

Optionally install JQ an lightweight and flexible command-line JSON processor for test the backend API.

- login as `root`
- update all installed Debian packages: `apt-get update; apt-get upgrade`
- install JRE from Debian repository: `apt-get install openjdk-17-jre-headless`

example output

```
root@satnms7-dev:/home/satnms# apt-get install jq
...
The following NEW packages will be installed:
  jq libjq1 libonig5
...
```

Now install the ***sat-nms*** backend software package:

- upload `satnms4-backend` package to `/home/public on the target system
- login as `root`
- install the local satnms4-backend package

`apt install /home/public/satnms4-backend_[version].deb` .

example output

```
root@satnms7-dev:/home/public# apt install ./satnms4-backend_1.17.10-1_all.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'satnms4-backend' instead of './satnms4-backend_1.17.10-1_all.deb'
The following NEW packages will be installed:
  satnms4-backend
0 upgraded, 1 newly installed, 0 to remove and 1 not upgraded.
Need to get 0 B/24.7 MB of archives.
After this operation, 0 B of additional disk space will be used.
Get:1 /home/public/satnms4-backend_1.17.10-1_all.deb satnms4-backend all 1.17.10-1 [24.7 I
Selecting previously unselected package satnms4-backend.
(Reading database ... 38210 files and directories currently installed.)
Preparing to unpack .../satnms4-backend_1.17.10-1_all.deb ...
Unpacking satnms4-backend (1.17.10-1) ...
Setting up satnms4-backend (1.17.10-1) ...
```

On success you will find a new directory `/home/satnms/backend/` which contains the software and configuration files.

5.3.4 Configuration

A ***sat-nms*** backend service provides a gate to all ***sat-nms*** MNC servers in your overall system. This could be just a single MNC service running on the same host as the backend (all-in-one server) or any number of MNC service distributed over your network.

There are three steps to configure the ***sat-nms*** backend service:

1. create configuration file `/home/satnms/backend/backend.properties`
2. modify configuration file
3. enable autostart of backend service

By default the `satnms4-backend` package delivers a sample configuration for an all-in-one server installation. This template can be found in `/home/satnms/backend/backend.properties.default` . You can use this template by copy it to real backend configuration file: `/home/satnms/backend/backend.properties` and then editing it regarding you requirements.

To enable a minimal backend setup with a MNC service running on localhost just use the provide template:

```
satnms@satnms7-dev:~/backend$ cp backend.properties.default backend.properties
```

A detailed description of all options from `backend.properties` is available in the administration manual.

To ensure the backend service will automatically start on reboot, login as root and enable this service.

- login as `root`
- enable autostart with `systemctl enable backend"

Now you can start the backend service as user `satnms` and check if its running.

- login as `satnms`
- run the `satnms-watch`

```
┌──────────────────────────┤ sat-nms state ├──────────────────────────┐
│                                                                     │
│  hostname / MNC name : satnms7-dev / MNC                            │

│                                                                     │
│          refresh      refresh service states                        │
│          satnms-start start MNC Service                             │
│          backend-stop stop Backend Service                          │
│          nginx-start  start Nginx Webserver                         │
│                                                                     │
│          <Select service>          <Exit>                           │
└─────────────────────────────────────────────────────────────────────┘
```

The output depends on the installed services. In the example above, only the ***sat-nms*** backend service is installed and running.

You can also control the backend service directly with the follwing commands:

- start backend service `sudo systemctl start backend`
- stop backend service `sudo systemctl stop backend`

Check if the backend service start successfully:

- status of backend service `systemctl status backend`

```
satnms@satnms7-dev:~/backend$ systemctl status backend
● backend.service - sat-nms MNC Backend
     Loaded: loaded (/etc/systemd/system/backend.service; disabled; preset: enabled)
     Active: active (running) since Fri 2025-02-14 16:06:10 UTC; 5min ago
   Main PID: 18136 (java)
      Tasks: 22 (limit: 2307)
     Memory: 136.9M
        CPU: 8.788s
     CGroup: /system.slice/backend.service
             └─18136 java -Djava.security.egd=file:/dev/./urandom -jar backend.jar
```

You can test if the backend is ready to reply on REST-API requests use the heathcheck API-Endpoint which does not require authentication. It requires `jq` and `curl` installed. Run: `curl -k https://localhost:8443/healthcheck | jq` and if should report some information about the running backend software.

```
satnms@satnms7-dev:~$ curl -k -s  https://localhost:8443/healthcheck | jq
{
  "dict": [
    {
      "key": "PRODUCT",
      "val": "satnms4 backend"
    },
    {
      "key": "WEBSITE",
      "val": "www.satnms.com"
    },
    {
      "key": "VERSION",
      "val": "1.17.10 2024-12-17 12:22:54"
    },
    {
      "key": "SERIALNO",
      "val": "000001"
    }
  ]
}
```

Logfiles are available:

- `cat /home/satnms/backend/backend.log`
- `journalctl -u backend`

A detailed description how to run the ***sat-nms*** backend service is available in the administration manual.

Troubleshooting

If you have trouble to connect to the backend server's API endpoints check first if the backend service is still running with:

- `systemctl status backend` or
- `/home/satnms/backend-stat`

Additionally you can lookup the process ID (PID) of the backend service process:

```
satnms@satnms7-dev:~$ ps axu | grep backend.jar
satnms   18136  0.3  8.4 2606224 170268 ?   Ssl  16:06   0:25 java -Djava.security.egd=file:/d
```

Now check if the backend process with this PID (here 18136 from the second column) is associated to a process listening on the TCP port 8443:

```
satnms@satnms7-dev:~$ ss -taunp |grep 8443
tcp   LISTEN 0      100    *:8443     *:*    users:(("java",pid=18136,fd=10))
```

The backend internal web server runs on Port 8443 and serves only HTTPS requests. You should that this process is `LISTEN` on all interfaces (`*:8443`)

5.4 Installation SatDB database

This section provides installation instructions for the PostgreSQL database used by the***sat-nms*** Monitoring & Control System.

PostgreSQL is a free and open-source relational database management system. Installation packages are available for different operating systems and Linux distributions. The following chapter descripes the installation on Debian Linux 12 with the PostgreSQL version 15.

Details about PostgreSQL: https://www.postgresql.org/

If you have your own PostgreSQL installation or PostgreSQL cluster running on a different host or as a cloud service, you can skip the chapter Installation and move directly to chapter Configuration.

To update the database schema, we are using the Golang-Migrate tool. Details can be found here: https://github.com/golang-migrate/migrate.

Quick access links to the main sections of this installation guide:

- Database Installation
- Add database user
- Create SatDB database

The following topics will be covered by the Administration Manual

- Update SatDB database TODO LINK !!!
- Backup and restore SatDB database TODO LINK !!!

5.4.1 Requirements

- Minimal Debian 12 Installation and console or SSH access
- headless installation is sufficient
- root permission in Linux either via `su` or `sudo`
  - all examples in this manual assume that you get root shell with the `su` command
  - for installation with no direct `root` login, you have to add `sudo` in front of all commands which requires `root` permission
- access to Debian 12 repositories either via Internet or from a local Debian archive mirror
  - check with `apt-get update` access to the configured repository is available.
- for SatDB database setup: `satnms4-satdb_[version].deb` package (in the following referred to as `satnms4-satdb`)

5.4.2 For the impatient

This section provides a quick installation guide for the impatient and experienced Debian Linux users. Detailed information are in the following chapters.

```
apt-get update
apt-get upgrade
apt-get install postgresql
apt install /home/public/migrate.linux-amd64.deb
apt install /home/public/satnms4-satdb_[version].deb
```

5.4.3 Installation

Two external tools must be installed:

1. PostgreSQL
2. Golang-Migrate

Debian provided installation packages (`.deb`) for PostgreSQL.

- login as `root`
- update all installed Debian packages: `apt-get update; apt-get upgrade`
- install PostgreSQL from Debian repository: `apt-get install postgresql`

example output

```
satnms@satnms7-dev:~$ su -
Password:
root@satnms7-dev:~# apt-get update
Hit:1 http://security.debian.org/debian-security bookworm-security InRelease
Hit:2 http://deb.debian.org/debian bookworm InRelease
Hit:3 http://deb.debian.org/debian bookworm-updates InRelease
Reading package lists... Done

root@satnms7-dev:~# apt-get upgrade
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Calculating upgrade... Done
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.

root@satnms7-dev:~# apt-get install postgresql
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
The following additional packages will be installed:
  ... postgresql-client-15 postgresql-client-common postgresql-common ...
The following NEW packages will be installed:
  ... postgresql-client-15 postgresql-client-common postgresql-common ...
0 upgraded, 17 newly installed, 0 to remove and 0 not upgraded.
Need to get 49.1 MB/49.1 MB of archives.
After this operation, 200 MB of additional disk space will be used.
Do you want to continue? [Y/n]
... downloading and installing packages ...
```

By default Linux user `postgres` has access to the database from `localhost` only without password.

To test if the PostgreSQL database was installed and started successfully, you can connect with command line tool `psql` (in short CLI):

- login as `root`
- switch to the PostgreSQL user: `su - postgres`
- run the PostgreSQL interactive terminal: `psql`
    - installed version will be show
    - an interactive prompt is available
- leave PostgreSQL terminal with `\q`
- switch back to user root: `exit`

example output

```
root@satnms7-dev:~# su - postgres
postgres@satnms7-dev:~$ psql
psql (15.10 (Debian 15.10-0+deb12u1))
Type "help" for help.

postgres=# \q
postgres@satnms7-dev:~$
```

To install Golang-migrate you need to manually download the Debian AMD64 package

- download debian package `migrate.linux-amd64.deb` from https://github.com/golang-migrate/migrate/releases/
- upload to target system in `/home/public`
- install the package with `apt-get install /home/public/migrate.linux-amd64.deb`

example output

```
root@satnms7-dev:~# apt-get install /home/public/migrate.linux-amd64.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'migrate' instead of '/home/public/migrate.linux-amd64.deb'
The following NEW packages will be installed:
  migrate
0 upgraded, 1 newly installed, 0 to remove and 0 not upgraded.
Need to get 0 B/16.2 MB of archives.
After this operation, 53.2 MB of additional disk space will be used.
Get:1 /home/public/migrate.linux-amd64.deb migrate amd64 4.18.1 [16.2 MB]
Selecting previously unselected package migrate.
(Reading database ... 55809 files and directories currently installed.)
Preparing to unpack .../public/migrate.linux-amd64.deb ...
Unpacking migrate (4.18.1) ...
Setting up migrate (4.18.1) ...
```

You can test the successfull installation with `migrate --version` which should display the installed version number, e.g. 4.18.1

5.4.4 Configuration

If PostgreSQL is installed you need to setup an user and a database for the ***sat-nms*** MNC system. These setups will be automatically performed if you install the `satnms4-satdb` package . Installation instructions for system where you are not able to install our Debian package, manual instructions are included in the following chapters.

The ***sat-nms*** MNC system will use the user `satnms` to connect to the database. This user will also be the owner of the SatDB. This prevents the application from requiring administrative rights for the entire database and the MNC system can use the same PostgreSQL database

engine together with other software.

The ***sat-nms*** MNC system will use a database with the name `satnms`. If you are using you own PostgreSQL installation, make sure that this database name is not already used by any other application.

- upload the `satnms4-satdb` to /home/public on the target system running PostgreSQL.
- login as `root`
- install the local satnms4-satdb package `apt install /home/public/satnms4-satdb_[version].deb`. During installation you will be prompted for a password. The default password in preinstalled systems delivered by SatService is `satnms`. Please change it to secure your system.

example output

```
root@satnms7-dev:~# apt install /home/public/satnms4-satdb_0.2.0-1_all.deb
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
Note, selecting 'satnms4-satdb' instead of '/home/public/satnms4-satdb_0.2.0-1_all.deb'
The following packages were automatically installed and are no longer required:
  libwpe-1.0-1 libwpebackend-fdo-1.0-1
Use 'apt autoremove' to remove them.
The following NEW packages will be installed:
  satnms4-satdb
0 upgraded, 1 newly installed, 0 to remove and 2 not upgraded.
Need to get 0 B/5,304 B of archives.
After this operation, 0 B of additional disk space will be used.
Get:1 /home/public/satnms4-satdb_0.2.0-1_all.deb satnms4-satdb all 0.2.0-1 [5,304 B]
Selecting previously unselected package satnms4-satdb.
(Reading database ... 159218 files and directories currently installed.)
Preparing to unpack .../satnms4-satdb_0.2.0-1_all.deb ...
checking user 'satnms' ...
checking postgresql ...
/var/run/postgresql:5432 - accepting connections
checking migrate ...
check database user 'satnms' ...
create PostgreSQL user 'satnms' ...
Enter password for new role:
Enter it again:
check database 'satnms' ...
Unpacking satnms4-satdb (0.2.0-1) ...
Setting up satnms4-satdb (0.2.0-1) ...
installing SatDB database schema ...
1/u init_satdb (26.36938ms)
2/u init_satdb (29.867137ms)
```

Remark: the default password in preinstalled systems delivered by SatService is `satnms` . Please change it to secure your system.

5.4.5 PostgreSQL network configuration

By default, access to the PostgreSQL database engine is restricted to the local system (the system where the database is installed) and no remote access via network is possible. If the ***sat-nms*** MNC system is a all-in-one installation this default configuration is sufficient and you can skip this chapter.

For a distributed MNC installation network access from a different host must be possible. Usually the database runs on the central server and the connected MNC servers needs to access the database via network.

- login as `root`
- edit the file `/etc/postgresql/15/main/pg_hba.conf`
  - if a different version of PostgreSQL is installed replace `15` with the version number
  - add a line at the end of the file with `host all all [local-net] md5`
    - where [local-net] is the network from where you want to connect e.g `192.168.2.0/24`
- edit file `/etc/postgresql/15/main/postgresql.conf`
  - uncomment and change line to: `listen_addresses = '*'`
- restart PostgreSQL: `systemctl restart postgresql`

example from pg_hba.conf

```
# allow access for two additional networks
host    all             all             172.17.1.0/16           md5
host    all             all             192.168.1.0/24          md5
```

example from postgresql.conf

```
# - Connection Settings -
listen_addresses = '*'   # what IP address(es) to listen on;
port = 5432              # (change requires restart)
```

You can test the network configuration with from any other system with an installed `psql` tool, or even on the local system if you specify the IP address of your PostgreSQL server:

- login as user `satnms`
- test connection: `psql --host [server-ip-address]`

example output

```
satnms@satnms7-dev:/etc/postgresql/15/main$ psql --host 192.168.2.231
Password for user satnms:
psql (15.10 (Debian 15.10-0+deb12u1))
SSL connection (protocol: TLSv1.3, cipher: TLS_AES_256_GCM_SHA384, compression: off)
Type "help" for help.
satnms=>
```

5.4.5.1 Change users password

To avoid that the clear text password appears in the CLI history, you can use the `\password` command in `psql`.

- login as `root`
- switch to user the PostgreSQL user: `su - postgres`
- run `psql`
- enter command `\password satnms` which prompts you for a new password

example output

```
postgres@satnms7-dev:~$ psql
psql (15.10 (Debian 15.10-0+deb12u1))
Type "help" for help.

postgres=# \password satnms
Enter new password for user "satnms":
Enter it again:
postgres=# \q
```

5.4.6 Manual configuration

You can skip this section if you successfully installed the `satnms4-satdb` package.

5.4.6.1 Manual add database user

New users can be created via CLI or with SQL statements. This manual uses the CLI tool. There is no difference between database actions or CLI command, `createuser` is just a wrapper around the SQL command `CREATE ROLE`.

- Roles subsumes users and groups, so to be precises we are create a new role and not a user
- CLI https://www.postgresql.org/docs/current/app-createuser.html
- login as `root`
- switch to user the PostgreSQL user: `su - postgres`
- run `createuser --interactive --pwprompt` to create a new user

- name: `satnms`
- password: [set your own password here]
- be superuser: `no`
- allow to create databases: `no`
- allow to create more new roles : `no`

example output

```
root@satnms7-dev:~# su - postgres
postgres@satnms7-dev:~$ pwd
/var/lib/postgresql
postgres@satnms7-dev:~$ createuser --interactive --pwprompt
Enter name of role to add: satnms
Enter password for new role:
Enter it again:
Shall the new role be a superuser? (y/n) n
Shall the new role be allowed to create databases? (y/n) n
Shall the new role be allowed to create more new roles? (y/n) n
```

5.4.6.2 Create SatDB database

New databases can be created via CLI or with SQL statements. This manual uses the CLI tool. There is no difference between database actions or CLI command, createdb is just a wrapper around CREATE DATABASE

- Database must be named `satnms` and the owner of this database must be the role `satnms` as created above
- before you try to to create the database, make sure there exist no database with the same name.
- CLI: https://www.postgresql.org/docs/current/app-createdb.html
- create database: `createdb satnms "sat-nms MNC database"`

example output

```
TODO
```

5.4.6.3 Load SatDB database schema

To initialize the newly create database with all the required object definitions (schema) the installed `migrate` tool will be used. This tool needs the schema definition files `*.sql`) which are installed by the `satnms4-satdb` package to `/home/satnms/satdb/` . Usually this package automatically runs the database migration steps, but if this fails you will find below how to run the step manually.

You can check the current database version with:

```
migrate -database 'postgres://satnms:satnms@localhost:5432/satnms?sslmode=disable' -path
```

- copy migration files to `/home/satnms/satdb/`
  - for each migration (aka database version) two files exists
    - `[number]_init_satdb.up.sql`
    - `[number]_init_satdb.dow.sql`
- run migration script to apply the changes.
  - `up` command migrates to the latests version
  - execute this as user `satnms`, its not necessary to switch to user `postgres` because the database and role `satnms` are already created in the previous steps.
  - `migrate -database 'postgres://satnms:satnms@localhost:5432/satnms?sslmode=dis`

Remark: If the database is already initialized it will only run the migration for the new version(s). E.g. if already database version 2 is installed and there are migration files for version 3 and 4 it will upgrade the database to version 4.

example output

```
satnms@satnms7-dev:~$ migrate -database 'postgres://satnms:satnms@localhost:5432/satnr
1/u init_satdb (81.381471ms)
2/u init_satdb (96.040331ms)
satnms@satnms7-dev:~$
```

5.4.6.4 Force database version

In case a migration step fails, migrate will not let you run other migrations on the same database and will mark the database as dirty. You have to fix the migration and then force the corresponding version.

- run `migrate -database 'postgres://satnms:satnms@localhost:5432/satnms?sslmode=disable'`
- replace [number] by the database version you want to force. e.g. `1`

5.4.6.5 Delete database user

If you created a user by mistake you can remove it. For details refer to the PostgreSQL manual:

- CLI: https://www.postgresql.org/docs/current/app-dropuser.html
- `dropuser` is a wrapper around `DROP ROLE`

example output

```
postgres@satnms7-dev:~$ dropuser --interactive satnms
Role "satnms" will be permanently removed.
Are you sure? (y/n) y
```

5.4.6.6 Remove database

If you created a database by mistake you can remove it. For details refer to the PostgreSQL

manual:

- CLI https://www.postgresql.org/docs/current/app-dropdb.html
- `dropdb` is a wrapper around `DROP DATABASE`

6 Theory Of Operation

This section gives some background information about the internal structure and some functional concepts of the M&C software. It may be helpful to know how things work under the hood - both for operating and especially for configuring the software.

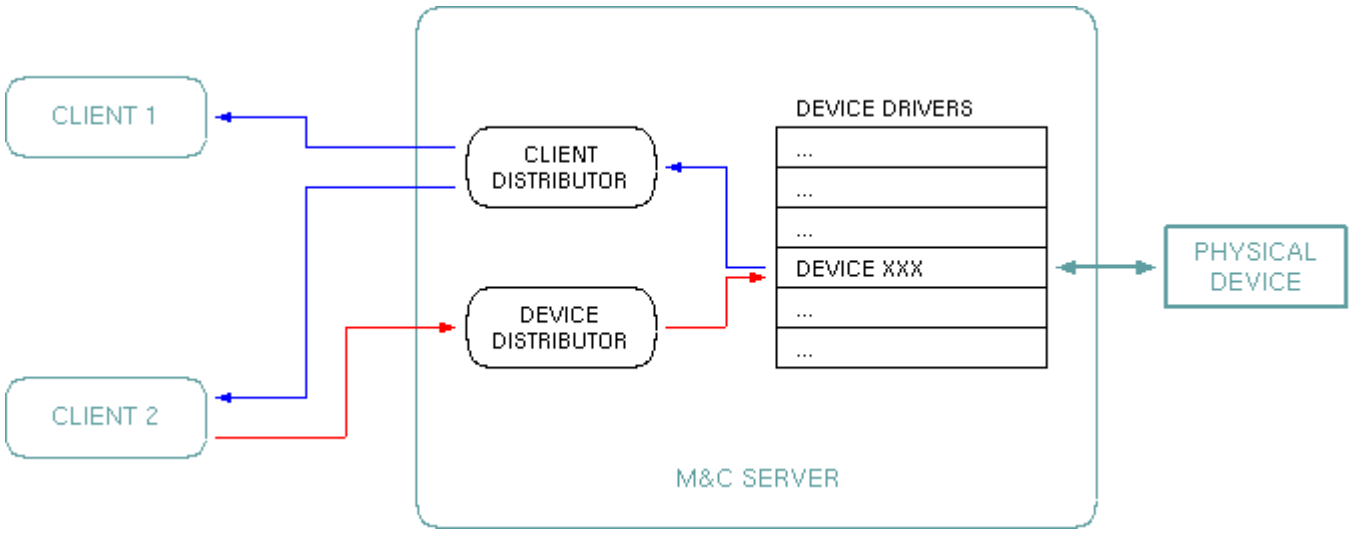
- Chapter M&C Concept describes the basic concepts how a parameter setting at a particular device finds its way to the user interface, how device drivers work and how the M&C software handles the data read from and sent to a device internally.
- Chapter Event Logging describes the functions of the event log database in the M&C software. Event logging happens in a persistent, rotating database of a fixed size (in days of stored events), it supports storing the event logs of multiple M&C systems at a single place.
- Finally, chapter Automating Procedures With Macros gives some information woh the macro feature in the M&C software works as well as examples how to edit macros in the editor or write the mfrom scratch.

All this information refers to the legacy java client of the software but it applies to the web based user interface as well.

6.1 M&C Concept

The following paragraphs give a short introduction to the M&C software's architecture and explains some basic concepts of it. Here a digest in advance:

- The M&C software is built in a client - server architecture. The server dealing with the direct equipment control is a stand alone program running on that machine providing the hardware interfaces which control the equipment. Apart from this, the user interface is another program talking to the server by messages over an TCP/IP channel. A user interface program (client) may run on the M&C server itself or on any other machine having a network connection to the M&C server. There may be multiple clients connected to the same server at a time.
- As mentioned above, messages are used for the communication between the client and the server. Moreover, most of the internal communication between the server's components are done by messages, too. Messages report parameter settings or status information when sent to a client and the transport commands the operator enters at the user interface to the server. Chapter Parameter Messages explains this messaging mechanism more detailed.
- Within wide parts of the software, equipment settings are treated as abstract values. The M&C server uses pluggable modules called 'device drivers' to translate these values to commands the physical device understands. Device drivers are user configurable and user extensible, making the software highly adaptable. Chapter Device Drivers explains this device driver concept



To deepen the explanations given above, this diagram shows a simple configuration with two clients (user interfaces) connected to a M&C server. With this example the flow of information shall be explained.

The first situation which shall be shown, is the polling of status information from the controlled device. The M&C software (more precisely: the device driver) polls all status information and all equipment settings on a regular basis. Control parameters like a frequency or data rate setting are polled less frequently, as they are not expected to change by themselves. At this point we will look to a frequently polled parameter like a lock alarm flag. The device driver polls this flag once a second. With each cycle the following actions are performed:

1. The device driver sends a command string to the device, reads the response and decodes the 'lock alarm: yes/no' information from the device's reply.
2. The device driver codes this information to a parameter message and forwards the message to the 'message distributor'.
3. The message distributor looks in it's message memory for the previous value of this message. If there is a previous message and it contains the same state of this lock alarm, nothing happens. The distributor suppresses multiple messages with the same contents. If however the value has changed, the distributor remembers the new value and sends a copy of this message to every client which is interested in this parameter. In this case both clients will receive a message with the new lock alarm state.

Changing an equipment setting on an operator's request happens in a similar way. After the operator entered the new value at the user interface, the following steps are made by the software:

1. The client software codes the value entered by the operator to a message. It sends this message to the M&C server.
2. At the server, the 'device distributor' receives this message and routes is to the device driver of interest.
3. The device driver receives the message and notes it down.
4. Synchronized with it's polling activities, the driver picks up the changed value and translates it to a command string understood by the physical device. It sends this

command string and processes the device's acknowledgment.

5. Now the device driver triggers an extra polling cycle for the parameter it just has written. This way the parameter is read back and distributed in the same manner described above for the lock alarm fault flag.

6.1.1 Parameter Messages

Parameter messages are one of the basic concepts of the software. They are used to transport parameter settings and status information between the components of the software.

A Message is composed of a message identifier and the value which shall be transported. The latter can be a text string, an enumerated value, a numeric value (integer or floating point) or a boolean flag. The message ID indicates the source or destination of the message.

Message identifiers

The message identifier defines the device driver variable, this message belongs to. Depending on the direction in which the actual message is sent, this can be the recipient of the message or the originating variable.

A message identifier is a textual string composed of two or more words which are separated by dots. The first of these words is the name of the device, the remaining part of the identifier is the name if the device driver variable. A message identifier ' **MODEM-1.tx.on** ' refers to the variable ' **tx.on** ' at the device '**MODEM-1** '.

The usage of messages for parameter settings

Picking up the example with the '**MODEM-1.tx.on** ' parameter, the following shall explain what happens, if a parameter is changed by the operator. The user interface window containing this parameter sends a message to the M&C/VLC server which dispatches the message to the device driver variable which listens to messages with this identifier. The device gets the new value and sets it at the device. The value will be read back (immediately after it has been set, but in regular intervals, too) and a message with the value read from the device is distributed to all windows showing this parameter.

Range messages

Well, but how does the user interface 'know' that '**MODEM-1.tx.on** ' is a CHOICE parameter with the possible selection OFF or ON?. It does not know this from it's own, it receives a so called *range message* from the device driver with this information. A range message describes the data type and the valid range of a parameter. It uses the message ID of the parameter it describes with a ' **.R** ' appended. The range message for the parameter above would use the identifier ' **MODEM-1.tx.on.R** '. The message contents describes the '**MODEM-1.tx.on** ' parameter as a (OFF/ON) choice parameter.

A device driver distributes range messages for all variables it maintains. It tells the user interface about the presence type, and range of all it's parameters. Two important consequences of this fact are:

- The user interface screen dealing with a certain device type, can be used for more than one variants of this type, as the parameter ranges (bit rate ranges, clocking options or something else) are defined on runtime by the device driver rather than by the user interface screen itself. The latter acts as a template which gets filled with the range definitions of an individual device.
- A device driver is not limited to distribute range messages once at start up. The driver may change the range of particular parameters dynamically on the state of other parameters. A common example is to enable/disable certain parameters completely, depending on the presence of some hardware options a device provides.

Message transport

Messages are transported within the software over TCP/IP streams. They can be sent within the same software component, from one sub-component to the other. But they also carry their information between the M&C/VLC server and the user interface program (client) which may be on another computer located somewhere completely different.

To to reduce the number of messages which are sent, the software uses some Optimizations, two of them are listed below:

- Messages are distributed only to the recipients which explicitly requested for them. This is done with a subscription mechanism: If for example a window gets opened which shall display the ' **MODEM-1.tx.on** ' parameter mentioned above, the window *subscribes* for the reception of this parameter. The window in turn gets a message with the actual value of this parameter and -- every time this parameter changes -- another message which updates this parameter. When the window closes, it voids this subscription.
- The message distribution agents in the software suppress messages which are identical. Hence, if a Eb/No value gets polled at a modem once a second, the user interface will get this message only if the value changes.

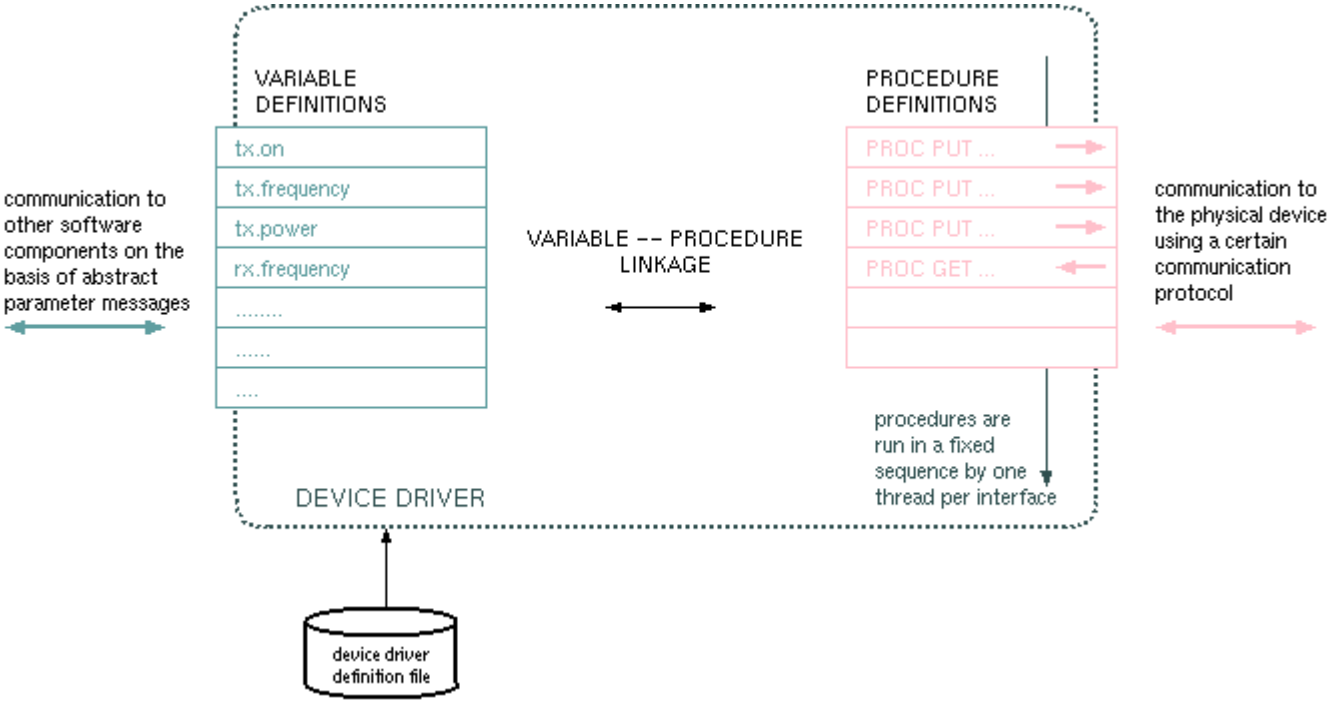
6.1.2 Device Drivers

Device drivers in the M&C software translate abstract parameter settings which are represented by parameter messages into commands sent to the physical device and vice versa. The basic idea is to modularize the software in a way, that one device in a station setup can be replaced by another model, perhaps even by a model made by another vendor, simply by selecting another device driver.

The sat-nms M&C advances this concept by introducing a 'universal device driver' which is completely user configurable. The configurable device driver let's you write your own device drivers for device models which are not yet supported by the software. Most of the device drivers coming with the software are built on top of this configurable driver, so there are a lot of examples you can use as a template.

The universal device driver

The figure below illustrates the structure of a device driver built with the 'universal device driver'. The principal function, however, applies to 'hard coded' drivers, too.



To other software components (primarily to the user interface) the device driver interfaces by a list of variable definitions. On the other hand, a list or procedures does the 'real work', translating the abstract parameter values to physical command sequences. In between a function here called 'variable -- procedure linkage' defines which procedure is run to set or read a certain parameter.

With the universal device driver, all this is setup (compiled) during the program initialization from a text file which describes the device driver in special, but quite simple programming language.

Variables

Variables are the interface between the device driver and the other components of the software, specially the user interface. Each variable acts as an end point for a parameter message. It may receive messages -- which causes the driver to set this parameter at the physical device -- but also may send it's parameter message in order to tell the user interface about the actual setting of this parameter. Chapter ' Device Driver Variables ' explains this more detailed.

Procedures

There are two types of procedures a driver may define. A 'PUT' procedure sends one or more parameters to the physical device after coding them into the format the physical device expects. A 'GET' procedure sends a request to the device, reads the reply and decodes one or more variable values from the data received. A procure never can be both, 'PUT' and 'GET' at the same time.

The driver's environment in the software provides one program thread for each physical interface (e.g. RS232 port). Within this thread all procedures of all device drivers communicating through this interface are called in a fixed sequence. The threads are running concurrently, utilizing the computer's capacity for one thread while another is waiting for a device's reply. Chapter ' Device Driver Procedures ' gives more information about how procedures work.

Special types of device drivers

Not all device drivers are implemented by means of the universal device driver. On the one hand there are a couple of devices which use such a trick method for their remote control, that the universal device driver is not capable in handling this.

The other and larger group of 'hard coded' drivers comprises the so called *logical devices* . These devices do not communicate directly with a physical device, they in fact combine parameter messages in some way and send the result to other device drivers. Power control loops or a software based automatic redundancy switching device are two common examples for this driver family.

6.1.3 Device Driver Variables

Variables are the interface between the device driver and the other components of the software, specially the user interface. Each variable acts as an end point for a parameter message. It may receive messages -- which causes the driver to set this parameter at the physical device -- but also may send it's parameter message in order to tell the user interface about the actual setting of this parameter.

Inside, a variable separately stores two values: The value which recently has been commanded and the value which has been read from the device during the previous polling cycle. By managing these values separately, the device driver is able to check if a value has properly been set by the device. If you see messages like 'Parameter some.name set to X but reads Y' in the event log, then the parameter polling which followed a command returned a value different from the commanded one.

6.1.4 Device Driver Procedures

The software basically knows two types of procedures: A 'PUT' procedure sends one or more parameters to the physical device after coding them into the format the physical device expects. A 'GET' procedure sends a request to the device, reads the reply and decodes one or more variable values from the data received. A procure never can be both, 'PUT' and 'GET' at the same time.

As mentioned in chapter 'Device Drivers' , all procedures of the driver are called on a regular basis. The procedures are called in the same sequence as they appear in the driver definition file. Procedures which actually have no work to do, are skipped by the driver.

A procedure links to one or more variables, the 'WATCH' statement in the driver definition file defines the variables a procedure shall link to. Thereby, a procedure may link to multiple variables but each variable may be 'watched' at maximum by one 'GET' and one 'PUT'

procedure. If now one of the 'watched' variables receives a new value an operator wants to set at the device, the variable marks the 'PUT' procedure which it is linked to as 'dirty'. With the next cycle, the driver recognizes this flag and does *not* skip the procedure this time.

Hence, setting the parameter at the physical device by the procedure happens not synchronously when the parameter message arrives. The physical equipment setting is done decoupled from the arrival of the message, but synchronized with the polling activities the device driver does on a regular basis. This ensures, that the device driver always finishes any pending polling command before it sets a parameter at the device.

While the method of a dirty flag for a 'PUT' procedure is a quite simple rule to determine which procedure shall be run and which shall be skipped, things are a little bit more complicated with 'GET' procedures. There also is a 'WATCH' statement for 'GET' procedures, but the dirty flag is managed in a more sophisticated way here:

1. When the program starts, all 'GET' procedures wake up with the dirty flag set. The driver has to inquire all parameters from the device when it starts.
2. The same applies after a communication failure. If the device didn't answer for some time, an operator might have replaced a faulty device against a new one which will have different settings. The device driver marks all 'GET' procedures as dirty if a communication failure occurs.
3. Each variable contains a timer, programmed for CYCLE interval, the driver description file individually defines for each variable. If the timer expires, the 'GET' procedure watching this variable is marked dirty. This way, each variable is read on a regular basis using an individual polling cycle.
4. Once a variable has been written to a device in a 'PUT' procedure, the 'GET' procedure watching this variable is marked dirty. This enforces a variable to be read back after it has been written to the physical device. This specially is important with variables having a quite long polling cycle programmed. A read back of the parameter eventually would happen minutes later.

6.2 Event Logging

The sat-nms software provides a elaborate event logging facility which lets the operator keep track of device faults and other events. It stores device fault messages and other events like the start of the software, user logins or the NMS communication connections to VLCs.

The ' Concepts ' chapter below explains how the event logging works with M&C systems and with VLC controlled by a NMS as well. Then the chapters ' The Event Report Window ', ' The Active Faults Window ' and ' The Live Event Log Window ' introduce the user interface to the event logging facility.

6.2.1 Concepts

The event log database in the sat-nms software stores device fault messages and other events. Each individual fault flag a device driver read from the device gets logged when it changes it's state. Beside this events like the start of the software, user logins or an NMS's communication connections to the VLCs are logged.

With device faults, not only the appearance of the fault is logged. Also the end of the fault state is logged by the device driver. The latter message also contains a note about the endurance of the fault state.

Event messages

Each message stored in the event log contains a time stamp, the message source, a message text and a priority value. The event priority tells about the importance of a event message.

- 'Informational' messages are of the lowest priority. Events which do not signal a fault like user logins are logged as informational messages. Also messages which indicate the end of a fault state are marked informational.
- 'Fault' messages (medium priority) signal the fault state of a device or software component.
- The highest priority level, 'Alarm' signal a severe fault which needs to be repaired immediately.

The sat-nms software with it's factory settings does not use 'Alarm'. The operator however can configure the priority of each fault flag in the system to his needs. With a NMS system, event priorities have an impact to the event transport to the NMS (see below).

With a M&C system, the event log is stored at the M&C computer. The user interface software provides a ' Event Report Window ' which lets the operator query the event database and aLive Event Log Window which displays the recent events in a scrolling list.

The event database is limited in size. It implements a circular buffer which automatically purges all events older than a configurable limit. The factory setting for event log depth is 365 days. The M&C or NMS system administrator may change this by modifying a configuration file.

Collecting events in the NMS

With a sat-nms network management system, the event log at the NMS site centrally stored the messages originated from all VLCs in the network. Each particular VLC uses a temporary buffer to hold it's events messages until it is able to send them to the NMS. In this case the event log stores additional data with each event:

- The originating VLC is stored as a second source field in each record.
- The time when the message arrives at the NMS is stored as a second time stamp.

The event queue in the VLC

Each VLC contains an event queue which intermediately stores event messages until they are sent to the NMS. The ' System ' device which is present in each VLC controls the behavior of this queue. It is essential to configure the parameters of an VLCs event queue when the VLC is setup, event messages may be lost if they are left unconfigured. This also applies to a M&C system, here the event queue must explicitly must be switched off by setting 'localhost' as destination and all threshold values to zero.

6.3 Automating Procedures With Macros

The sat-nms software includes a powerful macro recording and playback feature which lets you automate complex equipment settings to one mouse click. This feature is built on the parameter message concept of the software. Recording a macro means recording the parameter messages you sent when you change setting at the user interface.

The software stores recorded macros as plain text files, using a simple format which is easy to understand. This and some additional commands in macros, called 'macro directives', make the macro facility to a powerful tool:

- Macros may be edited for reworking or to create simple ones from scratch.
- Macros may be nested. Calling macros from inside macros lets you structure your macros in 'subroutines'
- Macros may contain 'formal parameters' which are substituted while the macro is executed.
- The execution of macros may be bound to buttons in user configured screens.

The following pages describe how macros work and how you use the functions in the software managing macro recording and playback.

6.3.1 Concepts

The M&C/VLC software uses parameter messages to transport equipment settings from the software's operator interface to the physical piece of equipment. Recording a macro simply means recording these messages to a file. Playing a macro sending again the messages from the recorded file.

Editing macros

A recorded message sequence is stored as a plain text file. This makes it easy to rework a recorded macro or even to write a macro from scratch. In a macro file all empty lines or comment lines (starting with a "#" character) are ignored. The other lines either contain equipment settings or macro directives .

Coding of equipment settings

In a macro, equipment settings always appear in the form

<message identifier> <value>

The message identifier consists of the name of the device which shall receive this setting followed by a dot and the parameter name to set. *MOD-2.tx.on* for example addresses the parameter 'tx.on' at the device named 'MOD-2'. A list of the parameter names recognized by the device types can be found at section ' Device Driver Index '. The device name in the macro may be an asterisk ('*') to indicate that this message shall be sent to all devices.

Macros vs. Device Presets

Macros and device presets both help you to automate extensive equipment settings. They work, however, completely differently:

- A device preset records the *state* of a device with all it's settings.
- A macro records the *changes* you apply to the device's settings.

To be sure that a device with all it's parameters is set to a certain state by a macro, you may apply a preset to the device while you record the macro. The macro will contain all settings from the preset.

6.3.2 Macro Directives

Beside plain definitions of parameter settings, a macro definition may contain a couple of additional commands called 'macro directives'. The macro processor recognized these directives and handles them separately. Directives all are lower case words starting with a percent character. The following directives are recognized:

%def

The %def directive defines a substitution parameter. The macro processor knows ten substitution parameters called 0..9. They work similar to parameters in shell scripts (Linux) or batch files (Windows). Any sequence of a percent character followed by a digit (%0 .. %9) in the macro gets substituted by the value defined in a %def directive before. The syntax of the %def directive is

%def [0..9] *substitution text*

For example, ' **%def 4 KSTAR-2** ' sets the substitution parameter '4' to the value 'KSTAR-2'. The character sequence '%4' gets replaced by 'KSTAR-2' in all equipment settings the follow this line in the macro. The substitution parameters are initially empty.

%inc

The %inc directive includes another macro definition at it's place when the macro is played. The syntax of the %inc directive is

%inc *macro-name*

You may nest the execution of macros up to eight levels deep using this directive. If the macro you reference does not exist, the directive is silently ignored.

A common practice of using included macros is to record basic equipment settings into a set of macros. Using the macro editor you can then create "super macros" which first call one ore more of the basic macros and finally set a couple of settings like the channel frequency or the transmit power explicitly.

%wait

The %wait directive lets you pause the execution of a macro for some time. The syntax of the %wait directive is

%wait *msecs*

where *msecs* is the time to pause in milliseconds. The paragraph 'Timing Issues ' below

explains why delays in the macro execution may be helpful.

6.3.3 Timing Issues

When executing a macro which sends equipment settings to more than one device, you might expect that the parameters are set in the same order they appear in the macro definition. In fact this is *not* the case, due to the parallel concept of the M&C software. The following example explains this issue:

```
#
# example macro definition
#

# switch off the carrier to avoid spurious transmissions
#
EIRP.on "OFF"

# turn the modulator to 8 MBit
#

# switch the carrier on again
#
EIRP.on "ON"
```

The example above which tries to clamp down the transmission while the modulator switches to another bit rate, definitely will not work as expected. The macro processor will send the settings in the order they appear to the M&C /VLC server. The latter receives the settings and passes them to the device drivers. Each device driver contains a buffer for the commands pending for execution. The driver for the EIRP setting and the modulator driver work in parallel. The driver for the TX-ON setting takes down the transmit power and immediately brings it up again. It does not wait until the modulator driver has finished the settings.

To overcome this problem, you should slow down the execution of the macro and insert %wait directives at the critical steps. Below the same example with programmed delays:

```
#
# example macro definition
#

# switch off the carrier to avoid spurious transmissions
#
EIRP.on "OFF"

# wait until the transmission is off
#

# turn the modulator to 8 MBit
#

# give the modulator 3 seconds to stabilize with the new bit rate
#

# switch the carrier on again
#
EIRP.on "ON"
```

7 Device Driver Reference

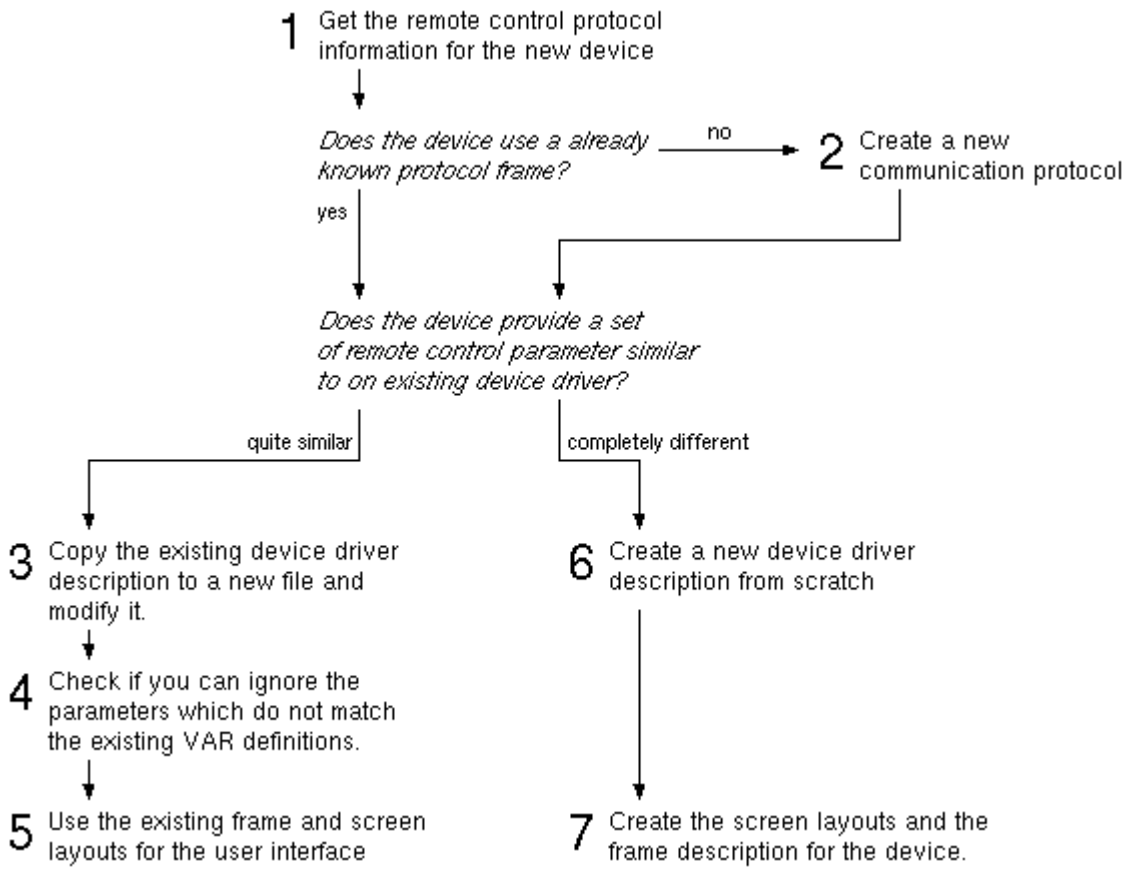
Device drivers in the MNC software translate abstract parameter settings which are represented by parameter messages into commands sent to the physical device and vice versa. The basic idea is to modularize the software in a way, that one device in a station setup can be replaced by another model, perhaps even by a model made by another vendor, simply by selecting another device driver.

The ***sat-nms*** MNC advances this concept by introducing a **universal device driver** which is completely user configurable. The configurable device driver let's you write your own device drivers for device models which are not yet supported by the software. Most of the device drivers coming with the software are built on top of this configurable driver, so there are a lot of examples you can use as a template.

To make the ***sat-nms*** software support an additional device type, the software needs at least three components:

1. A low level communication protocol which handles the protocol frame including device addressing or checksum calculation.
2. A device driver which defines the parameters the operator may inspect or control at the device. The device driver also contains the I/O routines to exchange these parameters with the device.
3. Finally, there must be a standard user interface (the so calleddevice oriented user interface) for the new device which lets an operator view or modify the device parameters.

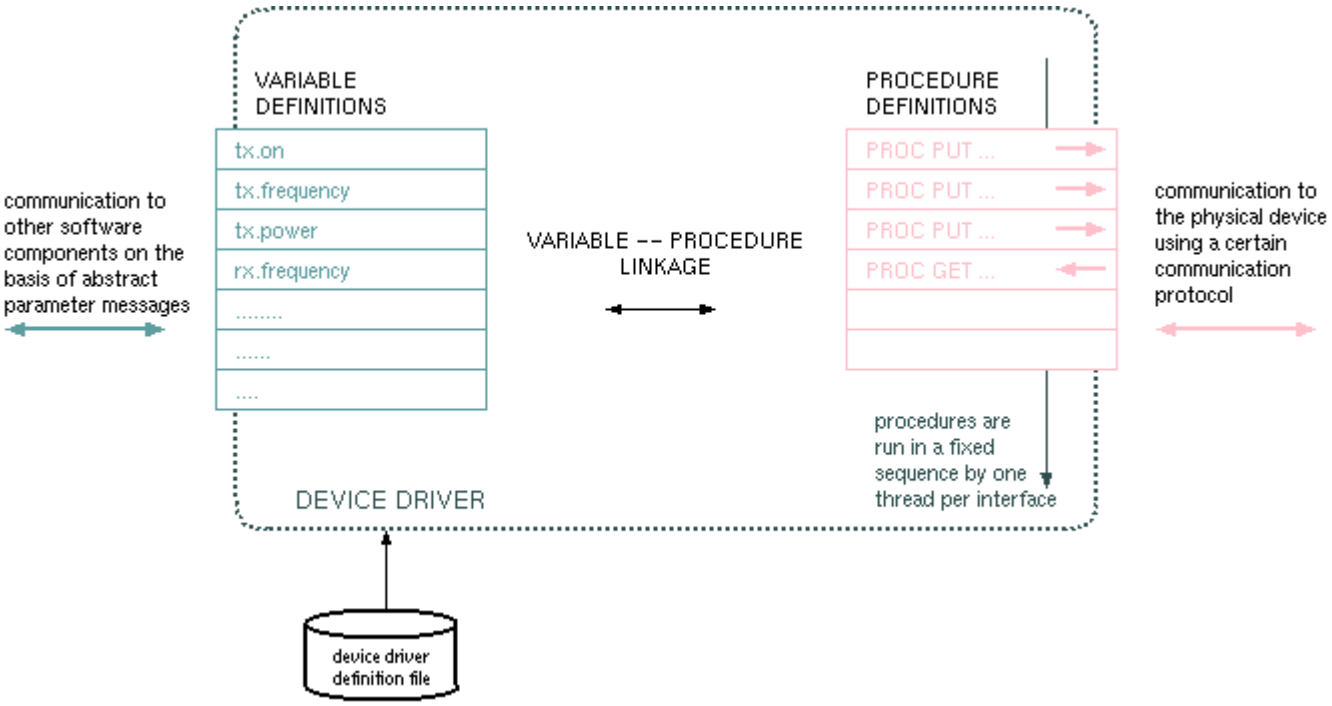
With the ***sat-nms*** software, all three components from the physical M&C interface at the device up to the representation of parameters on the screen are configurable and extensible by the customer. The ***sat-nms*** software comes with library supporting a large number of devices. These files are at your's disposal to use them as templates or as ready made module for the device driver you need to develop.



The diagram above illustrates the first steps to the integration of a new device type into the ***sat-nms*** software. You are encouraged to use as much as possible of the existing protocol, driver and user interface definitions.

7.1 Understanding the device driver

The figure below illustrates the structure of a device driver built with the**universal device driver**. The principal function, however, applies to 'hard coded' drivers, too.



To other software components (primarily to the user interface) the device driver interfaces by a list of variable definitions. On the other hand, a list of procedures does the 'real work', translating the abstract parameter values to physical command sequences. In between a function here called *variable -- procedure linkage* defines which procedure is run to set or read a certain parameter.

With the universal device driver, all this is setup (compiled) during the program initialization from a text file which describes the device driver in special, but quite simple programming language. The following pages describe how variables , procedures and the protocol encapsulation work together.

7.1.1 Variables

Variables are the interface between the device driver and the other components of the software, specially the user interface. Each variable acts as an end point for a parameter message. It may receive messages -- which causes the driver to set this parameter at the physical device -- but also may send it's parameter message in order to tell the user interface about the actual setting of this parameter.

Inside, a variable separately stores two values:

- The value which recently has been commanded and
- the value which has been read from the device during the previous polling cycle.

By managing these values separately, the device driver is able to check if a value has properly been set by the device. If you see messages like `Parameter some.name set to X but reads Y` in the event log, then the parameter polling which followed a command returned a value different from the commanded one.

7.1.2 Procedures

Driver procedures actually perform the communication with the device to control. They operate the device as commanded and poll the equipment settings and state.

There are two types of procedures a driver may define.

- A `PUT` procedure sends one or more parameters to the physical device after coding them into the format the physical device expects.
- A `GET` procedure sends a request to the device, reads the reply and decodes one or more variable values from the data received.

A procedure never can be both, `PUT` and `GET` at the same time.

The device driver executes the defined procedures in an endless loop, called the polling cycle. But a procedure is not necessarily called in every cycle. If there is nothing to do for a particular procedure, it is skipped. To determine which procedure must be executed in a cycle, procedures are bound to variables. A procedure may be bound to one or more variables, however, there may me at most one `PUT` and one `GET` procedure referencing a variable.

A `PUT` procedure is executed, if at least one of the variables it is bound to has received a new setting, e.g. from the user interface. For a `GET` procedure the following conditions cause the procedure to be executed:

1. The device driver has established communication to the device after power-on or after a communication interruption.
2. The (individually defined) polling interval for at least one of the variables bound to this procedure has elapsed.
3. At least one of the variables bound to the procedure has been commanded to the device. The parameter must be read back for verification.

7.1.3 Protocol encapsulation

The ***sat-nms*** device driver concept encapsulates the protocol frame used for the communication with a device in a separate layer. This protocol layer describes which kind protocol frame has to be wrapped around the commands sent to a device. There are a number of important advantages with this concept:

- The protocol frame is automatically added to each command or request sent to the device. The other way round, the driver automatically strips of this 'envelope' from the data received from the device.
- A certain type of protocol frame needs to be programmed only once and may be used for several device drivers, if for example different devices from the same vendor use one and the same protocol definition.
- Some devices may be operated either by one or the other communication protocol. The protocol encapsulation allows easily to switch between the variants.

With the ***sat-nms*** software, new protocol definitions may be added to the software, simply by editing a text file for the new type of protocol frame which is needed.

If you are going to write a new device driver, you first should investigate if there is an existing protocol definition in the ***sat-nms*** library which can be used to serve the new device. If no protocol definition matches, the chapter Device communication protocolsdescribes to write a new protocol definition.

7.2 Writing a device driver

As mentioned above, device drivers are coded as simple text files. When the MNC program starts, it 'compiles' the device drivers needed for it's equipment setup to memory. Writing a device driver means editing such a text file and storing it at a place in the MNC computer where the MNC program searches for device drivers.

The ***sat-nms*** device driver language has been designed to be very easy to understand. If you have a look at the device driver files coming with the ***sat-nms*** software, you probably will understand most of this language after an hour or two.

A MNC or VLC system keeps all device drivers in a subdirectory called `drivers`. On standard installations this is the directory `/home/satnms/drivers`. The name of the device driver files consist of the driver name (usually something like `Manufacturer-ModelNumber`) followed by the extension `.device`.

If you are writing the device driver on a Linux based MNC or NMS computer, you may want to use the VI text editor or mcedit (included in midnight commander) text editor for this. Both has been configured to colorize device driver files on these machines. We also providing syntax definitions for Visual Studio Code. Please ask your contact at SatService for details.

You also may copy device driver files to a MS-Windows based computer to edit them there. If you do this, you should consider the following:

- Device driver files are Unix based text files. Lines are terminated with a line-feed character only. Your favorite MS-Windows text editor may have problems to show these files.
- Unix / Linux is case sensitive with file names. Be sure that you don't mess up the case of characters in file name when you copy files between Unix and MS-Windows.

7.2.1 Starting from scratch

The following pages describe the 'hard way' to create a device driver from scratch. It is a good exercise to do this once for a simple driver. In practice however, in most cases you will use an existing driver as a template and modify this for your needs.

The basic steps to build a device driver from scratch are:

1. Naming the device driver
2. Selecting the communication protocol
3. Including the standard definitions file
4. Defining the driver variables
5. Adding the data exchange procedures

If you are reading this manual online, you may open theNDSatCom-KuBand-Upconverter driver example in a separate window to watch this in parallel while you are reading the following pages.

7.2.1.1 General file format

The ***sat-nms*** device driver language has been designed to be very easy to understand. The syntax resembles the BASIC programming language in some aspects, however, the language is highly specialized for it's purpose. Here some basic definitions which help you to read or write device driver files:

- The device driver language is case sensitive for all identifiers and keywords.
- Whitespace (space characters, tabs, line breaks) separates words.
- Line breaks have no special termination function.
- All keywords (except the RPN commands) are in upper case letters.
- Comments in C/C++ style are recognized (both, `/* ... */` and `// ...` comments).
- Identifiers (names for variables and tables) may consist of letters, digits and dots. They must start with a letter.

Beside the rules listed above, the device drivers provided by SatService GmbH follow some sort of coding/formatting convention:

- Each file starts with a comment block containing a short description and a change history.
- Identifiers always start with a lowercase letter. If a name consists of more than one word, the first letter of each following word is in upper case. Dots are used to group parameter functionally. Example: `mod.symbolRate` .
- Statements are indented four columns for each level.

7.2.1.2 Naming a device driver

To create a new device driver, the first step is to give the driver a name. The device drivers supplied by SatService GmbH all follow a 2 part naming scheme: `VendorName-ModelDescription` . A SatService ACU2 antenna control unit appears as `SatService-ACU2` in the device driver list. This makes it easy for the person who configures the equipment setup of a MNC system to select the appropriate device drivers.

The name of the device driver appears at several places:

- It is used as part of the device driver file name.
- Exactly the same name should be defined as a initialized variable called `info.type` . The online help function and the device preset directory selection of the user interface depend on this definition. Chapter Info variables gives more information about this.
- The COMMENT statement also contains the device driver name.

The COMMENT statement

The text following the COMMENT statement is free field and principally may contain any information. The device drivers coming with the ***sat-nms*** software all follow a convention which defines the comment string as

Driver-name X.YY YYMMDD

where X is the major version number of the driver, YY the minor version number and YYMMDD the release date of this driver version. It is recommended that customer defined device driver follow this scheme, too.

The comment statement in fact creates a hidden info-variable definition. This variable with the name `info.driver` is initialized with the comment text. At the Info-page of the device oriented user interface you can view the comment text or the driver name /version / date respectively.

Example

```
COMMENT   "NDSatCom-KuBand-Upconverter 1.03 010809"
```

This example, taken from NDSatCom-KuBand-Upconverter device driver, identifies this driver as version 1.03, released at August, 9th, 2001.

7.2.1.3 Selecting a communication protocol

With the ***sat-nms*** software, the device communication protocol handles the low level communication between MNC and device. There are trivial protocols which simply put a newline character at the end of each message and more sophisticated ones dealing with start/end characters, checksums, device addresses and more.

The ***sat-nms*** software comes with a bunch of predefined protocol definitions. If none of these protocol definitions matches, the chapter Device communication protocols describes to write your own protocol definition.

The communication protocol used for a certain device (for a certain serial interface, more exactly spoken) is defined with the equipment setup which you can configure a the graphical user interface. The device driver defines a preferred communication protocol. This means, in the device driver you state the communication protocol this driver is designed for. At the equipment setup screen of the software you still are able to choose a different protocol for a device of this type, however, you will be warned by the software. The preferred communication protocol for a device driver is defined with the PROTOCOL statement:

The protocol definition this statement refers to must exist in the `protocols` subdirectory of the software. On standard installations this is the directory `/home/satnms/drivers`.

Example

```
PROTOCOL  Miteq-MOD95
```

This example, taken from NDSatCom-KuBand-Upconverter device driver, defined the Miteq-MOD95 protocol as the preferred one for the driver.

Some communication protocols may be configured in some aspects of their functionality by applying protocol parameters to them. This is done with the `PROTOCOLPARAMETER` statement:

There may multiple `PROTOCOLPARAMETER` statements in on device driver file, each defining one aspect of the communication protocol. The `key` defines the parameter to set, `value` is the value to be assigned to this parameter. Please refer to the documentation of the protocol you are using (usually given in the comment section of the `*.proto` file) if there are configurable parameters for this protocol and if you need to set them for your application.

Protocol parameters may be set either in the protocol definition file (thus defining the parameter for all uses of the protocol) or in the device driver. A definition in the device driver overwrites the setting in the protocol file.

ATTENTION: If you have multiple devices in the same device thread (`INTERFACE`) using different device drivers, the result is unpredictable if the drivers do not make exactly the same protocol parameter settings.

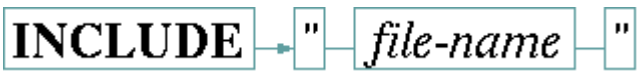
Example

```
PROTOCOLPARAMETER "post.content.type=application/xml"
```

7.2.1.4 File includes

ATTENTION: File including does not work when a device driver file gets interpreted by the *client* software, e.g. when a device preset shall be formatted along the device driver's parameter definitions. Variables defined in included files get not properly formatted in the device preset window. **For this reason it is recommended to use `INCLUDE` only for the standard includes as described in the example below!**

Device driver definition files may include other files. Frequently needed definitions may be encapsulated in included files which makes it easy to change these definitions at a central point. The syntax of the INCLUDE statement is:



The file name given in the INCLUDE statement is relative to the MNC software's home directory. With the ***sat-nms*** Software, there are two standard include files. Almost any driver provided by SatService GmbH includes one of these files. The files are named `Standard.inc` and

`StandardBin.inc` respectively. They define the so called low level interface to the device and the fault flags which indicate a communication failure for the device.

Example

```
INCLUDE   "drivers/Standard.dotinc"
```

This includes the standard ***sat-nms*** include file for driver which use a text based communication protocol. The file is located in the `drivers` subdirectory which is one level below the MNC software's home directory.

7.2.1.5 Tweaking the processing sequence

By default, the device driver executes the `PUT` and `GET` procedures in the same sequence, the procedures appear in the the driver file. Procedures which are not ready to run are skipped, but the overall sequence of execution is given by the order in which the procedure appear in the driver.

For PUT procedures this has the implication, that they are not executed immediately after an operator (or commanding device) has sent a new value for a parameter. The procedure has to wait it's turn. If there are a lot of `GET` procedures ready to run, this may take some time, specially with complex devices which are quite slow in response.

By specifying the `PUTPRIORITY` mode in the header of the device file, you can speed this up, making the device driver for a slow device more responsive:

You enable the `PUTPRIORITY` mode for a driver by adding `PUTPRIORITY` as a top level keyword to the driver file. This changes the order of execution of procedures in the following way:

If at least one `PUT` procedure of the driver is ready to run, all `GET` procedures are skipped. `GET` procedures only are executed if no `PUT` procedure is ready to run. The outcome of this is, that the `PUT` procedure is executed not later than the device thread's `IDLE` time after the new value has been commanded.

But as with most good things there is one hitch with this: If you change a parameter once every driver cycle of faster, `GET` procedures will never get a chance to run. The driver will respond quickly and execute any settings you command, but state information like alarms or meter readings will never be updated. This is the reason why `PUTPRIORITY` is not the default behavior of a ***sat-nms*** device driver.

7.2.2 Defining variables

Variables are the interface between the device driver and the other components of the software, specially the user interface. Each variable acts as an end point for a parameter message. It may receive messages - which causes the driver to set this parameter at the

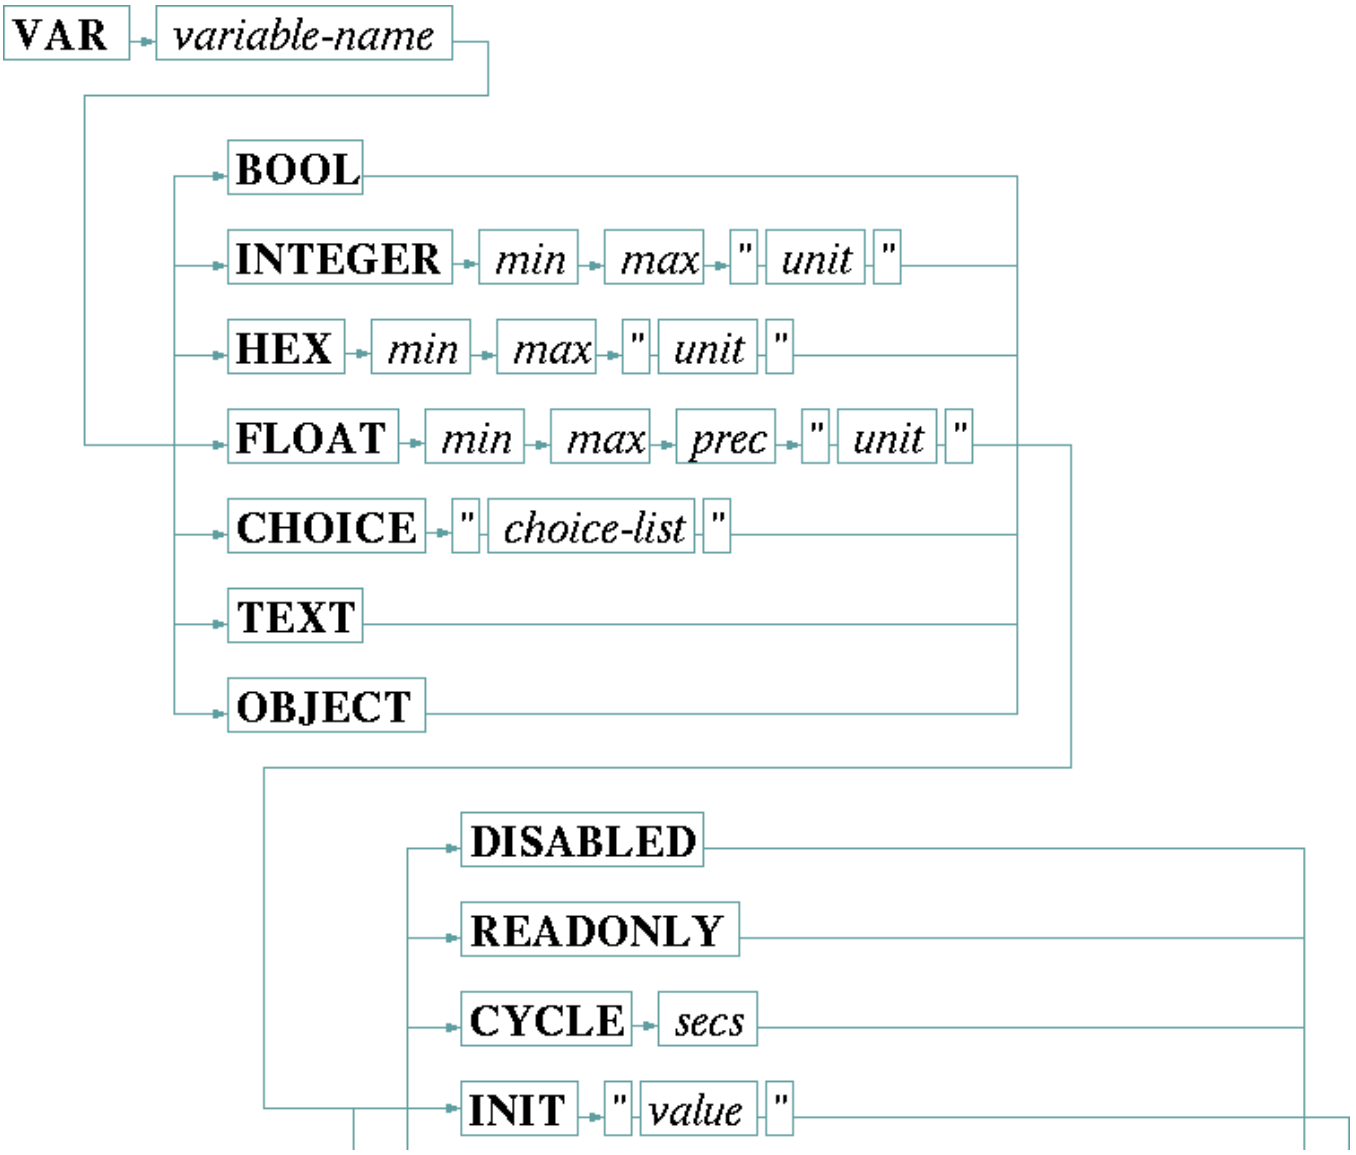
physical device - but also may send it's parameter message in order to tell the user interface about the actual setting of this parameter.

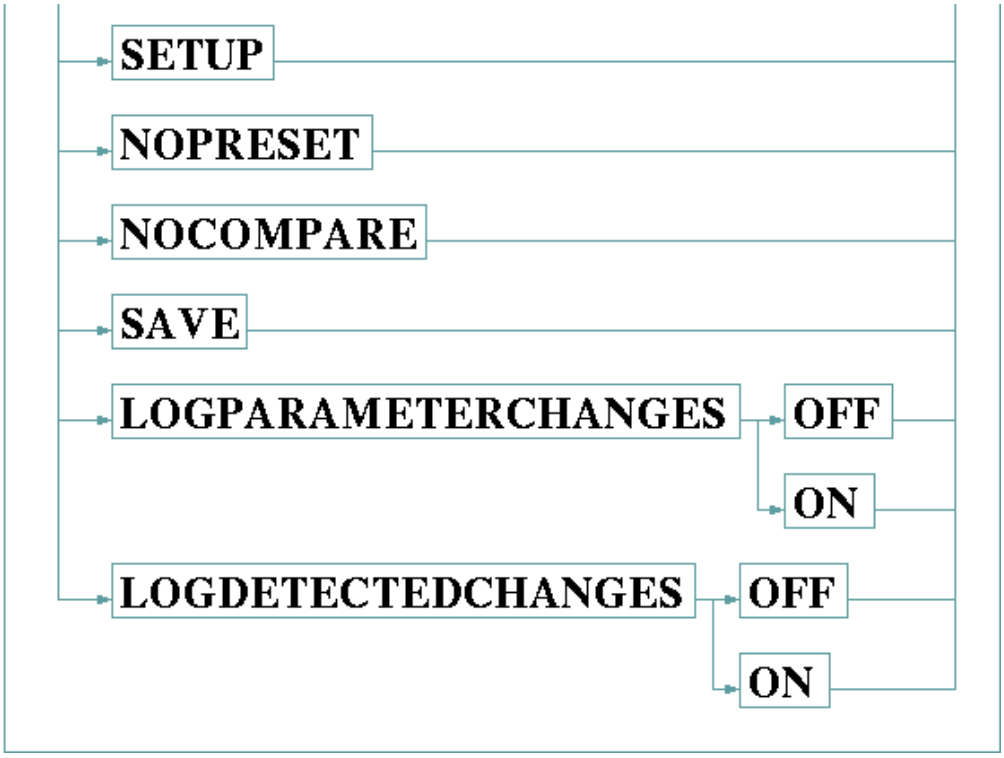
Before you start writing the device driver, you should plan a list of variables which build the software interface to the device. Designing this interface should be done careful, you can save a lot of effort if you are able to re-use variable definitions from other devices. This not only saves the time to write the definitions, it also enables you to use the parameter screens available for this device in the ***sat-nms*** library.

If you intend to write are driver for a device which implements similar functions as an existing driver, it is recommended to copy the variable list from this device.

7.2.2.1 The VAR statement

Device driver variables are defined using the `VAR` statement. With the `VAR` statement you define the name, the data type, the valid range and some other properties of the variable. This is the general syntax for a VAR statement:





A variable definition consists of the VAR keyword, the variable's name, a data type / range definition and optional modifiers which control the behavior of this variable.

Data type / range definition

The ***sat-nms*** device driver knows about 7 data types. The data type of a variable is defined by one of the data type keywords `BOOL`, `INTEGER`, `HEX`, `FLOAT`, `CHOICE`, `TEXT` or `OBJECT`, followed by the range definition for the selected data type. Here the data types listed in tabular form:

BOOL	The BOOL data type can have the values `true` and `false`. the `BOOL` type mainly is used for flags which shall be displayed as signal lamps at the user interface.
INTEGER	The `INTEGER` data type carries numeric integer values (64 bit length). When you define an `INTEGER` variable, you must provide the valid range (`min` / `max`) of the variable and a unit string which is shown at the user interface right of the data. If both, `min` and `max` are zero the user interface software does no range check at all. The unit string may be empty, but the double quotes are required ("").
HEX	The `HEX` data type also is a 64 bit integer, but formatted in hexadecimal notation.

FLOAT	The `FLOAT` data type carries double precision (64 bit length) floating point values. When you define a `FLOAT` variable, you must provide the valid range (`min` / `max`) of the variable, the number of fraction digits and a unit string which is shown at the user interface right of the data. If both, `min` and `max` are zero the user interface software does no range check at all. The unit string may be empty, but the double quotes are required (""). `FLOAT` variables are displayed with a fixed precision. Alternatively you may force a scientific notation by adding 100 to the precision value. Example: `VAR myFloat FLOAT 0 0 103 ""` defines a scientific formatted floating point variable shown with 3 digits precision (e.g. `0.123E-2`)
CHOICE	The `CHOICE` data type defines a parameter which may contain one of a fixed set of string values. You define this set as a comma separated list, enclosed in double quotes. At the user interface such a parameter appears as a drop down box where you can select a value from this list.
TEXT	The `TEXT` data type carries an arbitrary character string.
OBJECT	The `OBJECT` data type is used with complex variables which cannot be shown by the standard user interface routines. `OBJECT` variables only appear together with logical devices, you never will need this data type when writing a device driver.

Modifiers

Modifiers control some properties of a variable concerning it's state, usage, initialization and polling cycle. Modifiers may before or after the type definition.

DISABLED	Variables may be *enabled* or *disabled*. Disabled variables appear grey at the user interface, no value is displayed and no value may be entered. The `RANGESET` command is used to change the enable state. By default variables start in enabled state unless they are marked as `DISABLED` in the VAR statement. Disabling a variable at this point may be useful if the variable stands for a parameter which is not available at all models of the device type the driver is written for. The variable can be enables by the driver when it detects that the device actually connected to the MNC supports this parameter.

READONLY	Marking a variable `READONLY` prohibits the operator from changing it's value. This is used for state variables like meter readings. The range information for the data type used must be provided even if the variable is marked `READONLY`.
CYCLE	The `CYCLE` modifier controls the frequency (expressed as time interval in seconds), this variable shall be polled from the device. By default, variables are read from the device with every working cycle of the driver. This is about one a second if only a few parameters are to read. With many parameters the polling rate will be lower as the response time for each interrogation extends the cycle time.Hence, most device drivers poll only a few parameters like alarm flags or some meter readings with the maximum possible rate. Other parameters, e.g. settings you do not expect to change by themselves, are polled at a much lower rate.Setting the `CYCLE` time to zero causes the driver to do no regular polling for this variable at all. However, after power up and after communication failures, such a variable still is read once from the device
INIT	Using the `INIT` modifier, a variable may be initialized to a certain value. This value remains valid until the variable gets polled the first time. The `INIT` option often is used with variables which are used to configure the driver and never are read from the device itself.
SETUP	The `SETUP` modifier marks a variable to be listed in the maintenance/setup window of the standard device screens. Chapter Setup variables tells more about this special variable type.

NOPRESET	Using the `NOPRESET` modifier, a variable can be explicitly excluded from the set of parameters which are written to a device preset. A device preset contains all variables which define a `PUT` procedure and are no `SETUP` parameters and don't have the `NOPRESET` modifier set. The `reset` variable - if defined - is also implicitly excluded from device presets preset, for backward compatibility reasons. Please note, if you add `NOPRESET` to a variable in an existing device driver, this will not remove the value for this variable from existing device presets, it only will prevent the software from adding the value to new presets. You may use the preset editor to remove the unwanted value manually from existing device presets.
NOCOMPARE	Without the `NOCOMPARE` modifier the device driver will compare a value it commanded to the device against the value it read back after this. If the two values differ, an informational message showing the commanded and the read value is added to the log. `NOCOMPARE` suppresses this check. This is useful with parameters which are known for reading back in a wrong way, frequent messages in the log can be avoided this way.
SAVE	The `SAVE` modifier tells the driver to save this variable on disk and to restore it's value when the program starts. Usually all device settings are stored in the device itself, the MNC system does not change anything at a device when it starts.In some cases, e.g. with `SETUP` variables or if the driver implements a receive level threshold, it is useful to store variable values in the MNC system rather in the device.
LOGPARAMETERCHANGESON/OFF	Defines if this variables shall log changes which are commanded to it. Parameter changes are logged if this is set ON and the `logParameterChanges` switch in the device setup page is activated as well. `LOGPARAMETERCHANGES` is `ON` by default for all variables, hence you only need to state `LOGPARAMETERCHANGES OFF` for variables you want explicitly to be excluded from logging.

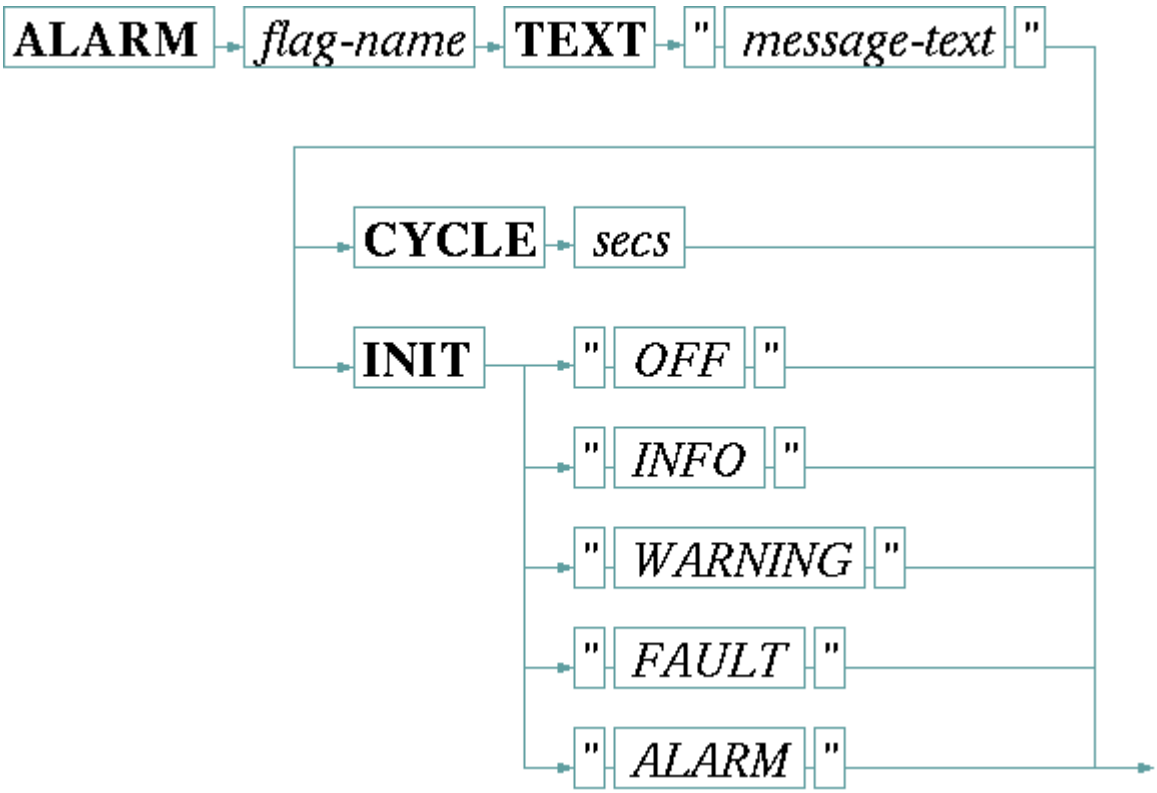
LOGDETECTEDCHANGESON/OFF	Defines if this variables shall log changes which are detected when reading back the values. Detected changes are logged if this is set ON and the `logDetectedChanges` switch in the device setup page is activated as well. `LOGDETECTEDCHANGES` is `ON` by default for all variables, hence you only need to state `LOGDETECTEDCHANGES OFF` for variables you want explicitly to be excluded from logging. Please note, the this modifier has no effect on read-only variables, they are not logged regardless of the logDetected setting.

Example

```
VAR audio.1.dotprogram      CYCLE 0   INTEGER 0 0 ""
VAR audio.1.dotrouting      CYCLE 0   CHOICE "NRM,MON,LFT,RGT"
VAR audio.1.dotoutput       CYCLE 0   CHOICE "ANALOG,AES/EBU,SPDIF,AC3"
VAR audio.1.dotlevel        CYCLE 0   INTEGER 6 18 "dB"
VAR audio.1.dotlanguage     CYCLE 0   TEXT
VAR audio.1.dottest         CYCLE 0   CHOICE "NRM,TEST-1,TEST-2,TEST-3,TEST-4,TEST-5"
VAR audio.1.dotinfo         CYCLE 4   TEXT READONLY
```

7.2.2.2 The ALARM statement

Alarm flags are a special variant of variables. They always are of the type `BOOL` and they are `READONLY`. For each `ALARM` variable you define a text message which appears in the *Faults* page of the device's user interface screen and as a message in the event log if the value of the flag changes. The device driver summarizes all alarm flags with each cycle and generates a summary fault information for the device. Alarm flags are defined with the ALARM statement:



An alarm flag definition consists of the `ALARM` keyword, the flag's name and an optional `CYCLE` definition which work analogous to the `CYCLE` modifier in a `VAR` statement.

The name of an alarm flag must be of the form `faults.XX` where `XX` is a two digit number in the range from 01 .. 98. The `faults.99` is reserved for a communication fault.

The alarm flag definition may include an INIT clause which initializes the fault priority value of the flag. INIT must be followed by one of `OFF`, `INFO`, `WARNING`, `FAULT` or `ALARM`.

Example

```
ALARM faults.01     TEXT "Remote access" INIT "WARNING"
ALARM faults.02     TEXT "Synthesizer"
ALARM faults.03     TEXT "LO-A lock"
ALARM faults.04     TEXT "LO-B lock"
ALARM faults.05     TEXT "Power supply"
ALARM faults.06     TEXT "IF-LO level"
ALARM faults.07     TEXT "RF-LO level"
```

7.2.2.3 Info variables

Each device driver defines a number of so called info variables which tell the operator, but also the client software about the device driver. All info variables

- are named starting with `info.`
- are defined `READONLY` The user interface contains a special screen which display the

contents of all info variables the driver defines.

Info variables are used to display information like device types, serial numbers etc. Beside this, there are three info variables each device driver **must** define in any case. They are:

info.type	This variable tells the user interface name of the device driver. It is used to select the subdirectory for device presets and to find the help screen for this device driver. `info.type` must be initialized to the name of the device driver which in fact is the file name with the trailing `.device` cut off.
info.port	This variable is set by the device driver to the name of the serial port which is used to access the device. This is for convenience, offering the operator this information without opening the device setup.
info.frame	The standard user interface uses the value assigned to this variable to select the 'device oriented' screen set for this device. `info.frame` must be initialized to name of the device frame definition file to be used with this device.

Example

```
VAR info.type          CYCLE 0 TEXT READONLY INIT "Tandberg-Alteia"
VAR info.port          CYCLE 0 TEXT READONLY
VAR info.frame          CYCLE 0 TEXT READONLY INIT "IRD-Alteia"
VAR info.model          CYCLE 0 TEXT READONLY
VAR info.serial        CYCLE 0 TEXT READONLY
```

The example above - taken from the Tandberg-Alteia device driver - identifies the driver as `Tandberg-Alteia` and tells the user interface to use the device oriented frame set called `IRD-Alteia` for this device. The info variables `info.model` and `info.serial` are set by the driver later, when it read the model description and serial number from the device.

7.2.2.4 Setup variables

Another group of variables which are treated specially by the driver are setup variables. They are used to configure the device driver or to set parameters which shall not appear at the standard user interface.

Setup parameters are shown in an own screen which is accessible only to operators of a privilege level of 150 and above. Setup variables must be marked with the `SETUP` modifier, the name of setup variables must start with `.config`.

Example

```
VAR config.lbandInputs    CYCLE 0 CHOICE "4,2" SETUP SAVE
VAR config.lnbPower       CYCLE 0 CHOICE "OFF,ON.,BST" SETUP
VAR config.loFreq         CYCLE 0 FLOAT 0 0 1 "MHz" SETUP
VAR config.berThreshold   CYCLE 0 TEXT SETUP
VAR config.sigThreshold   CYCLE 0 INTEGER 0 255 ""  SETUP
VAR config.errFrame       CYCLE 0 CHOICE "FREEZE,BLACK" SETUP
```

The example above - taken from the `Tandberg-Alteia` device driver - defines a setup variable `config.lbandInputs` which configures the driver for 2- or 4-input models of the IRD. This variable also is marked with the `SAVE` modifier to make the setting permanent. The following variables in the example are configuration settings which are placed in the setup area to keep them out from the common user interface.

7.2.2.5 Variables for internal use

Variables may be used to store intermediate values in the driver. For instance, a bit field status value may be read into a variable and then interpreted using the `BITSET` command.

Variables for internal use must be declared `READONLY` to work properly. Even though not required, it is recommended to give these variables a descriptive name which tells about the internal usage of this variable. The following example is taken from the SSE KStar device driver:

```
VAR internal.state HEX 0 0 " " READONLY   CYCLE 2

...

PROC GET WATCH internal.state
   PRINT "AL"
   INPUT "=" internal.state
   BITSET faults.01 = internal.state 9
   BITSET faults.02 = internal.state 15
   BITSET faults.03 = internal.state 11

...
```

7.2.3 Using conversion tables

`CHOICE` parameter often are implemented by the device's remote control protocol as numeric constants (0 for BPSK, 1 for QPSK) or they are abbreviated in a way which is hard to remember. The user interface of the software shall in contrast display self-explaining names for such settings.

The driver language lets you define translation tables which do such conversions while the driver performs a `PRINT`, `INPUT`, `READ` or `WRITE` statement. As the driver knows, in which direction a table translation must be done, you can use the same table to translate values when they are written to and when they are read from the device.

The TABLE statement described in following chapter is used to define translation tables.

7.2.3.1 The TABLE statement

The driver language lets you define translation tables which do such conversions while the driver performs a `PRINT`, `INPUT`, `READ` or `WRITE` statement. Tables are defined with the `TABLE` statement:

The `TABLE` keyword is followed by a name for this table and the table definition in double quotes. The table definition contains assignments `A=B`, separated by commas. Strings containing commas or equal characters cannot be translated through a table.

```
TABLE tModulation   "BPSK=BPS,QPSK=QPS,8PSK=8PS"
```

In the table definition, the `A` value is the string visible at the user interface of the software, the `B` value is used when communication with the device. The driver translates in a `PRINT` or `WRITE` statement BPSK -> BPS, QPSK -> QPS or 8PSK -> 8PS if the table `tModulation` shown in the example above is referenced. With an `INPUT` or `READ` statement, the table automatically translates the values the other way round.

For some applications a table definition may become quite large. The driver syntax permits to split up the table definition in multiple string/lines. Each string/line must be enclosed in double quotes and must contain at least one translation pair. Commas at the end of a line are omitted. Below an example for such a multi line table definition is shown.

```
TABLE tVideoTest   "NRM=00,625.1=01,625.2=02,625.3=03,625.4=04,625.5=05"
                   "625.6=06,625.7=07,625.8=08,625.9=09,625.10=10,625.11=11"
                   "625.12=12,625.13=13,625.14=14,625.15=15,625.16=16"
                   "525.1=17,525.2=18,525.3=19,525.4=20,525.5=21,525.6=22"
                   "525.7=23,525.8=24,525.9=25,525.10=26,525.11=27,525.12=28"
                   "525.13=29,525.14=30,525.15=31,525.16=32"
```

Remarks

- If a table translation is invoked with a value which is not contained in the table, the translation returns the first value in the table.
- To define a table it may be useful to copy the definition of the `CHOICE` variable which shall be translated at the place of the table statement. this copy then can be extended to the table definition.
- Don't add whitespace characters in the table definition to make this better readable. The driver would treat these characters as part of the strings to translate!

7.2.4 Adding data exchange procedures

While the device driver variables discussed in the chapters above specify the driver's interface

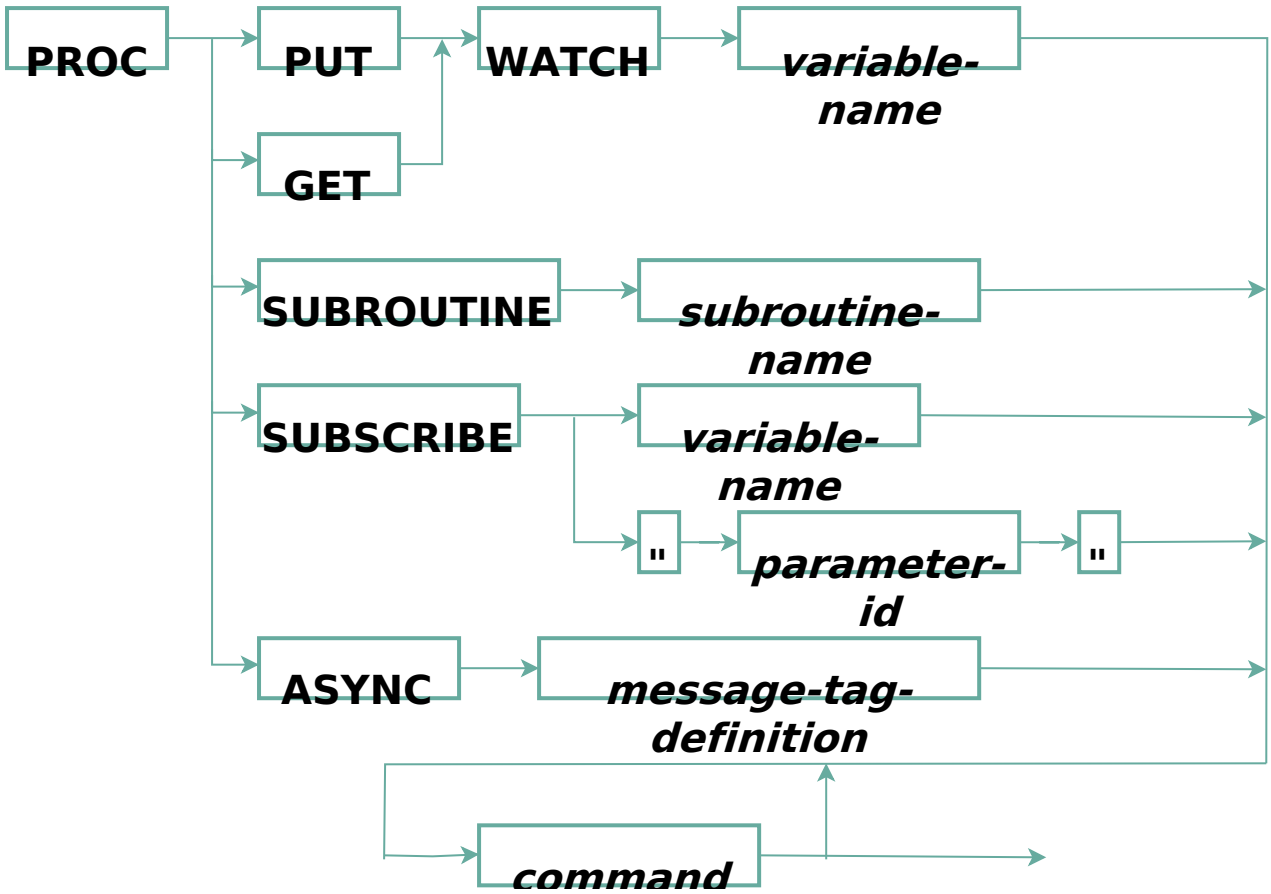
to the other parts of the software, does the device driver procedure implement the interface to the device itself. Based on the communication protocol selected in the equipment setup (the protocol handles the low level coding of the data exchanged with the device), procedures handle the chats done between the MNC and the device to perform parameter settings or to gain some information from the device.

The description of the PROC statement in the following chapter together with the examples supplied with this manual explain the usage of procedures. Generally the following rules apply to device driver procedures:

- Procedures are executed by the driver in the same order as they are defined in the driver specification.
- The driver knows GET-type procedures which read some information from the device into one or more variables and PUT-type procedures which send settings to the device.
- A procedure may handle one or more parameters.
- The driver skips any procedures where actually nothing is to do. For example a PUT-type procedure is skipped unless at least one of the values handled by it has been changed by the operator.
- A variable which has it's data source in the device must be handled at exactly one GET-type procedure.
- A variable being a device setting must be handled at exactly one PUT-type procedure.

7.2.4.1 The PROC statement

Driver procedures are defined with the PROC statement. The PROC keyword is followed by one of `PUT`, `GET`, `SUBSCRIBE`, `SUBROUTINE` or `ASYNC`. Chapter Using subroutines tells more about this type of procedures. `ASYNC` procedures handle messages sent by the device in an unsolicited way. Chapter ASYNC procedures. Procedures do not have an explicit*end* keyword, a procedure automatically ends where another definition (procedure, variable or table) starts.



`PUT` and `GET` procedures must have a `WATCH` keyword followed by one or more names of variables this procedure shall be bound to.

Generally, any variable which is referenced in a procedure must be defined before using the `VAR` statement. Although the driver language allows to define variables between procedures (a `VAR` statement closes an open procedure definition), the drivers supplied by SatService GmbH first define all variables and then all procedures for this reason.

Examples

There are two complete device drivers listed at the end of this section, showing several flavors of procedure definitions:

- NDSatCom-KuBand-Upconverter device driver
- Tandberg-Alteia device driver

Variable subscriptions

The `PROC SUBSCRIBE` variant of procedure definitions permits to react on changes of parameters controlled by other devices drivers. Such a procedure is called every time the referenced parameter changes. The parameter to listen to may be defined directly with its full parameter name in double quotes (e.g. `DEVICE.some.name`) or by the name of a variable in this device driver which contains the name of the parameter to listen to.

SUBSCRIBE type procedures are executed in the thread context where the parameter it's listening to is changed, not in the thread context of the local device driver. For this reason, `SUBSCRIBE` procedures never should contain IO-related statements like `PRINT`, `INPUT`, `READ`, oder `WRITE`. Communicating to the device from different program threads may break the communication protocol. That is much similar like when two people are talking at the same time, probably you won't understand any of them.

7.2.4.2 ASYNC procedures

Device drivers may define `ASYNC` procedures which handle messages sent by a device without a foregone request sent by the MNC. While the ***sat-nms*** device driver architecture is targeted to devices which only reply if requested to do this, `ASYNC` procedures provide a ways to handle unsolicited messages.

Basic concept

The concept behind `ASYN` procedures is a communication protocol which listens to the device all the time, reads all messages coming from the device. Each message is forwarded to the `ASYNC` procedures defined to check which procedure is in charge for this particular message.

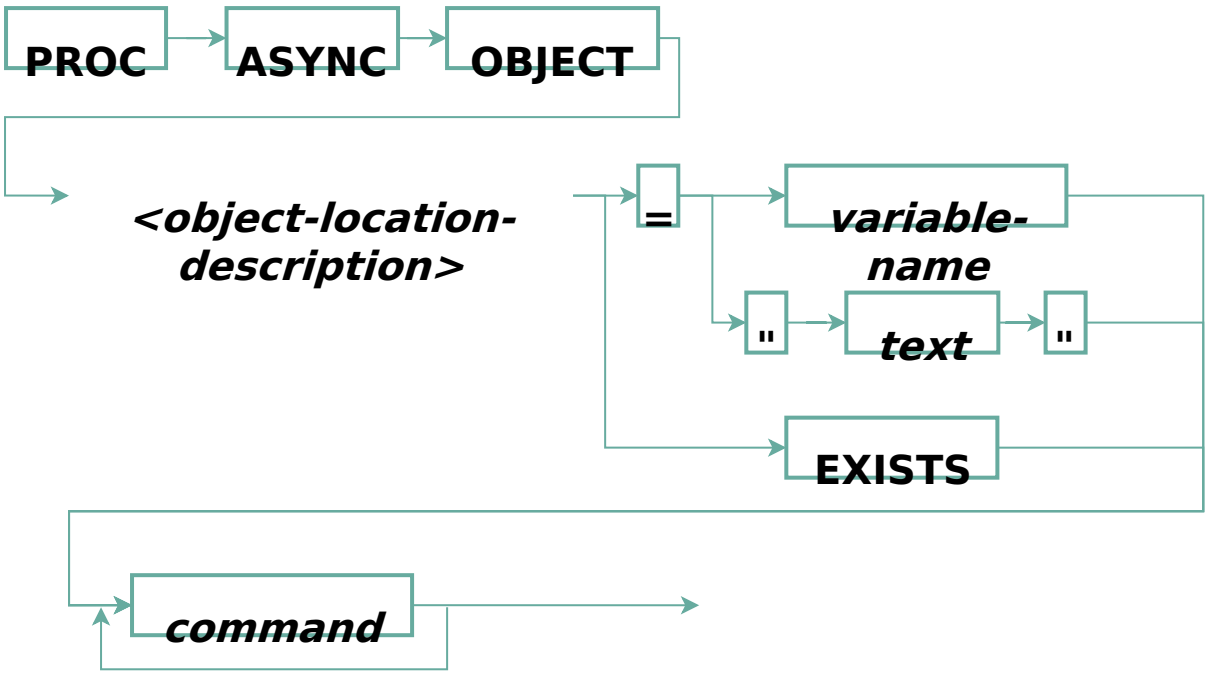
The check ist done by comparing so called message tags to a reference value defined for the procedure. For JSON based protocols the message tag is one value in the JSON document.

There are a number of constraints you have to consider if a device sends messages without being requested to, specially if the device responds to requests *and* sends unsolicited messages as well:

1. Reading data from a device asynchronously requires a ***sat-nms*** communication protocol definition that supports this. The protocol must listen to the device all the time and forward any incoming message to the device driver. If the protocol does not support this, no `ASYNC` procedures will be executed in a driver, even if they are defined.
2. You can no longer assume, that reading a device's reply after sending a request contains the expected data. You have to design the driver in a way, that all commands and status requests are sent in PUT procedures without reading the device's reply. All replies ans unsolicited messages have to be read in `ASYNC` procedures.
3. There are devices which provide separate communication channels for replies to requests and for asynchronous messages. With such a protocol the above restriction does not apply.
4. Commands and requests *never* must be sent from within an `ASYNC` procedure. As the `ASYNC` procedure runs asynchronously to the device driver thread, this may collide with commands sent from a `PUT` procedure.

PROC ASYNC for JSON coded protocols

For JSON based protocols the definition of an asynchronous procedure starts with the keywords `PROC ASYNC OBJECT`, followed by an object path definition as used with the `REST SET` and `REST PARSE` statements. You find an extensive description about the JSON object model and object paths in chapter 2.2.6 REST I/O functions

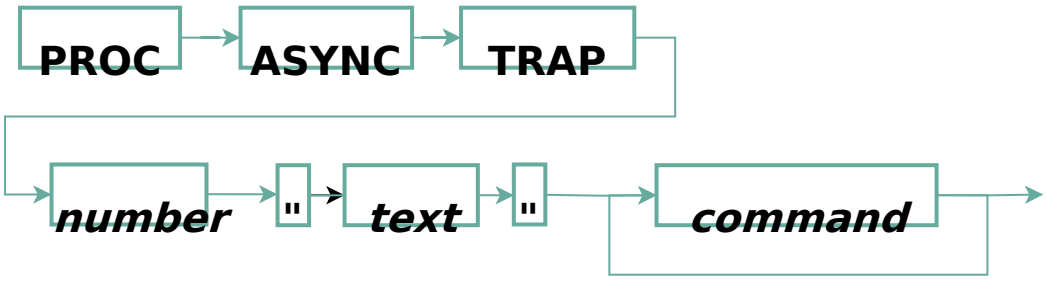


The object path definition is terminated either by the keyword `EXISTS` or a `=` character and the reference value this JSON object gets compared to. The reference value may be a quoted string or the content of a driver variable. The procedure body gets executed if the JSON object defined by the object path contains a value equal to the reference value following the `=` character.

If the keyword `EXISTS` is used, the procedure gets executed if an object at the given location exists in the message, the value assigned to it doesn't care.

PROC ASYNC for SNMP protocols

With SNMP, `PROC ASYNC TRAP` may be used to process traps issued by a device. The syntax for this kind of procedure is as follows:



The keywords `PROC ASYNC TRAP` are followed by the SNMP trap number and a pattern text. The SNMP trap calls this procedure if it has been issued from the IP address set for this device, the SNMP trap number matches the number stated with this procedure and the text submitted by the trap receiver contains the pattern text.

The trap receiver in the M&C software processes every trap it receives and translates it to a multiline string which is passed to the procedure(s) which are in charge for this trap. The first

line of this string contains the trap type, the IP address from which it was issued, the trap number and the specific number. If there are SNMP varbinds with this trap, for each varbind a line follows with the OID and the value if this varbind.

Example:

```
V1TRAP from 127.0.0.1 trapno=6 specific=99
1.3.6.1.4.1.53491.550.2.3.19.0=-76.33
1.3.6.1.4.1.53491.550.2.3.24.0=2
```

The varbinds may be interpreted with `INPUT` statements in the procedure body:

```
PROC ASYNC TRAP 6 "53491.550.2.3.19.0"
   INPUT "53491.550.2.3.19.0=" TRM 10 inputLevel
   INPUT "53491.550.2.3.24.0=" TRM 10 XLT tLock inputLock
```

The procedure above gets called for a trap (6) containing a varbind ending on "53491.550.2.3.19.0". The value of this varbind gets assigned to the driver variable *inputLevel*. The varbind ending on "53491.550.2.3.24.0" is assigned to 'inputLock' after translating it from the SNMP number encoding to the value expected in the driver. Using OID fragements starting with the deivce's enterprise ID is a reliable way to identify varbind OIDs in the trap text.

Remarks

- The trap number in the procedure header may be set to*to make the procedure accept any trap number. For SNMPv3 traps / informs the trap number must be *as SNMPv3 traps do not contain trap numbers.
- The pattern text in the procedure header may be set to "*" to accept any trap without checking if it contains the pattern text.
- `PROC ASYNC TRAP` procedures require the M&C server's trap receiver to setup properly. The file 'traprec.json' configures the properties of the trap receiver, the M&C user manual gives a conprehensive description of this configuration file.

7.2.5 Basic I/O functions

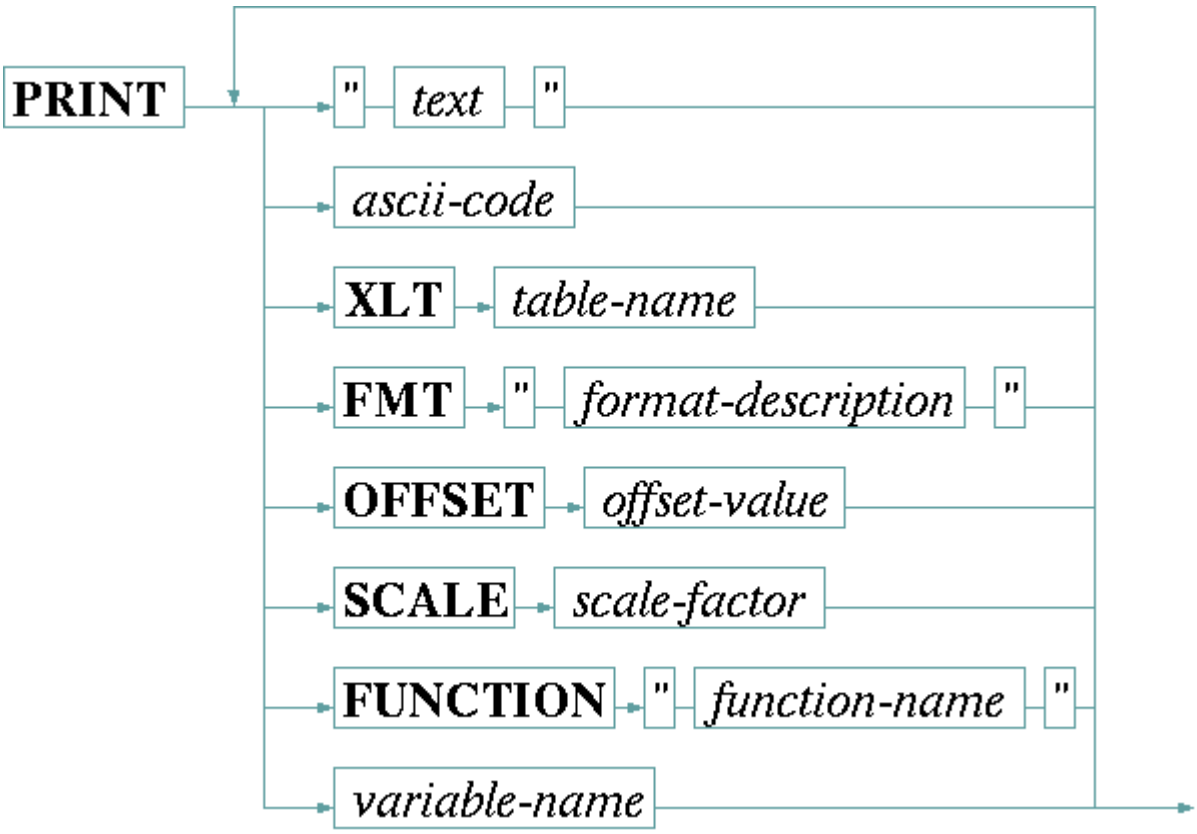
The primary function of a driver procedure is to acquire some information from the device (`GET` procedure) or to set one or more parameters from the data commanded somewhere else in the software (`PUT` procedure). The ***sat-nms*** device driver definition language provides four highly flexible statements for this purpose. They are:

PRINT	Composes/formats s (readable) string from multiple elements which may be text fragments, numbers (formatted in various ways), tokens from a `CHOICE` variable and more. The composed string is packed in a protocol frame and sent to the device. `PRINT` is used with devices which implement a text based protocol.

INPUT	The INPUT statement complements the PRINT statement. It reads a message from the device, strips off the protocol frame parses the received data according to the rules specified with the INPUT statement.
WRITE	The WRITE statement is the equivalent to PRINT for devices providing a binary communication protocol. WRITE sets up a binary data structure from constant and variable values, packs this structure in a protocol frame and sends it to the device.
READ	Reading data from a device providing a binary communication protocol is done with the READ statement. As the counterpart of the WRITE statement it reads a message from the device, strips off the protocol frame and provides means to interpret the received data as a binary structure variables.

7.2.5.1 The PRINT statement

The PRINT statement is used to send commands to a device which uses a text based protocol. It composes a command string from the elements following the the PRINT keyword, packs this string in the protocol frame defined by the communication protocol and sends this message to the device. The syntax of the PRINT statement is:



The table below describes the elements which may follow the PRINT keyword.

"text"	Plain text, enclosed in double quotes, is added to the output buffer as it is.

ascii-code	A decimal number is interpreted as the ASCII code of a single character to output. You may use this to send special characters like carriage-return or line-feed to the device.
XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the next variable value which shall be printed through this translation table. Chapter Using conversion tables gives more information about tables in general.
FMT "..."	The `FMT` keyword, followed by a format description in double quotes, tells the device driver to format the next variable following the format description given. `FMT` is used to format numeric variables into the representation the device expects in it's remote control command. `INTEGER` variables may be printed using a floating point format, and `FLOAT` variables may be printed with a `d` or `x` format likewise. With `FLOAT` variables you should format in any case as internal precision/rounding problems may cause unpredictable results when floating point values are printed unformatted.

A format description consists of the following elements:

format characters	description
d b x X f	The first letter of the format description defines the general number representation: `d` (decimal), `b` (binary), `x` (hex, lower case), `X` (hex, upper case) or `f` (floating point)
+	If the `+` option is given, the number is preceded by a +/- character even if it is positive. Together with the `0` option below, the sign appears as an additional character at the first column, hence the field width is increased by one on this case.
0	If the `0` option is given, the field is padded up with zeroes instead of spaces.
1 .. 99	Here follows a one or two digit field width. The field width is the total number of characters the formatted number occupies including the padding characters. If there are more digits needed to show a number correctly, the field with is enlarged automatically. Specifying a field width `1` disables the right orientation in a fixed width completely. This specially is useful for floating point numbers where only the number of fraction digits shall be fixed, not the complete field width.
.	For floating point formats the dot separates the precision from the field width.

format characters	description
0 .. 9	The dot is followed by a one digit specification of the number of fraction digits which shall be printed. The dot and fraction digits specification is valid only with the floating point format.

The table below describes the more elements which may follow the `PRINT` keyword.

OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, tells the driver to add the offset value to the next variable before it is printed.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, tells the driver to multiply the next variable with the scale factor before it is printed
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
variable-name	A variable name tells the driver to print the value stored in this variable. Usually the *commanded* value is used rather than the value which has been read back from the device. If, however, there has been never a value commanded, or if this variable is a read only variable, the value recently read from the device is used.

Before the variable is printed to the output buffer, any `XLT`, `FMT`, `OFFSET` or `SCALE` operations which have been specified are applied. This happens in a fixed order:

1. If a `SCALE` operation has been specified, this is done first.
2. The `SCALE` operation is followed by an `OFFSET` addition.
3. The so scaled value is processed through a `FUNCTION` if there is one.
4. The processed value is formatted according to a `FMT` specification if one is given.
5. Finally, the value gets translated through a translation table, if an `XLT` operation has been specified.

This scheme applies to numeric (`INTEGER`, `HEX`, `FLOAT`) and to text type variables as well. As soon as a `SCALE`, `OFFSET`, `FUNCTION` or `FMT` keyword is present in front of a variable, this gets converted to a floating point number. Strings which cannot be converted give a zero value.

Example

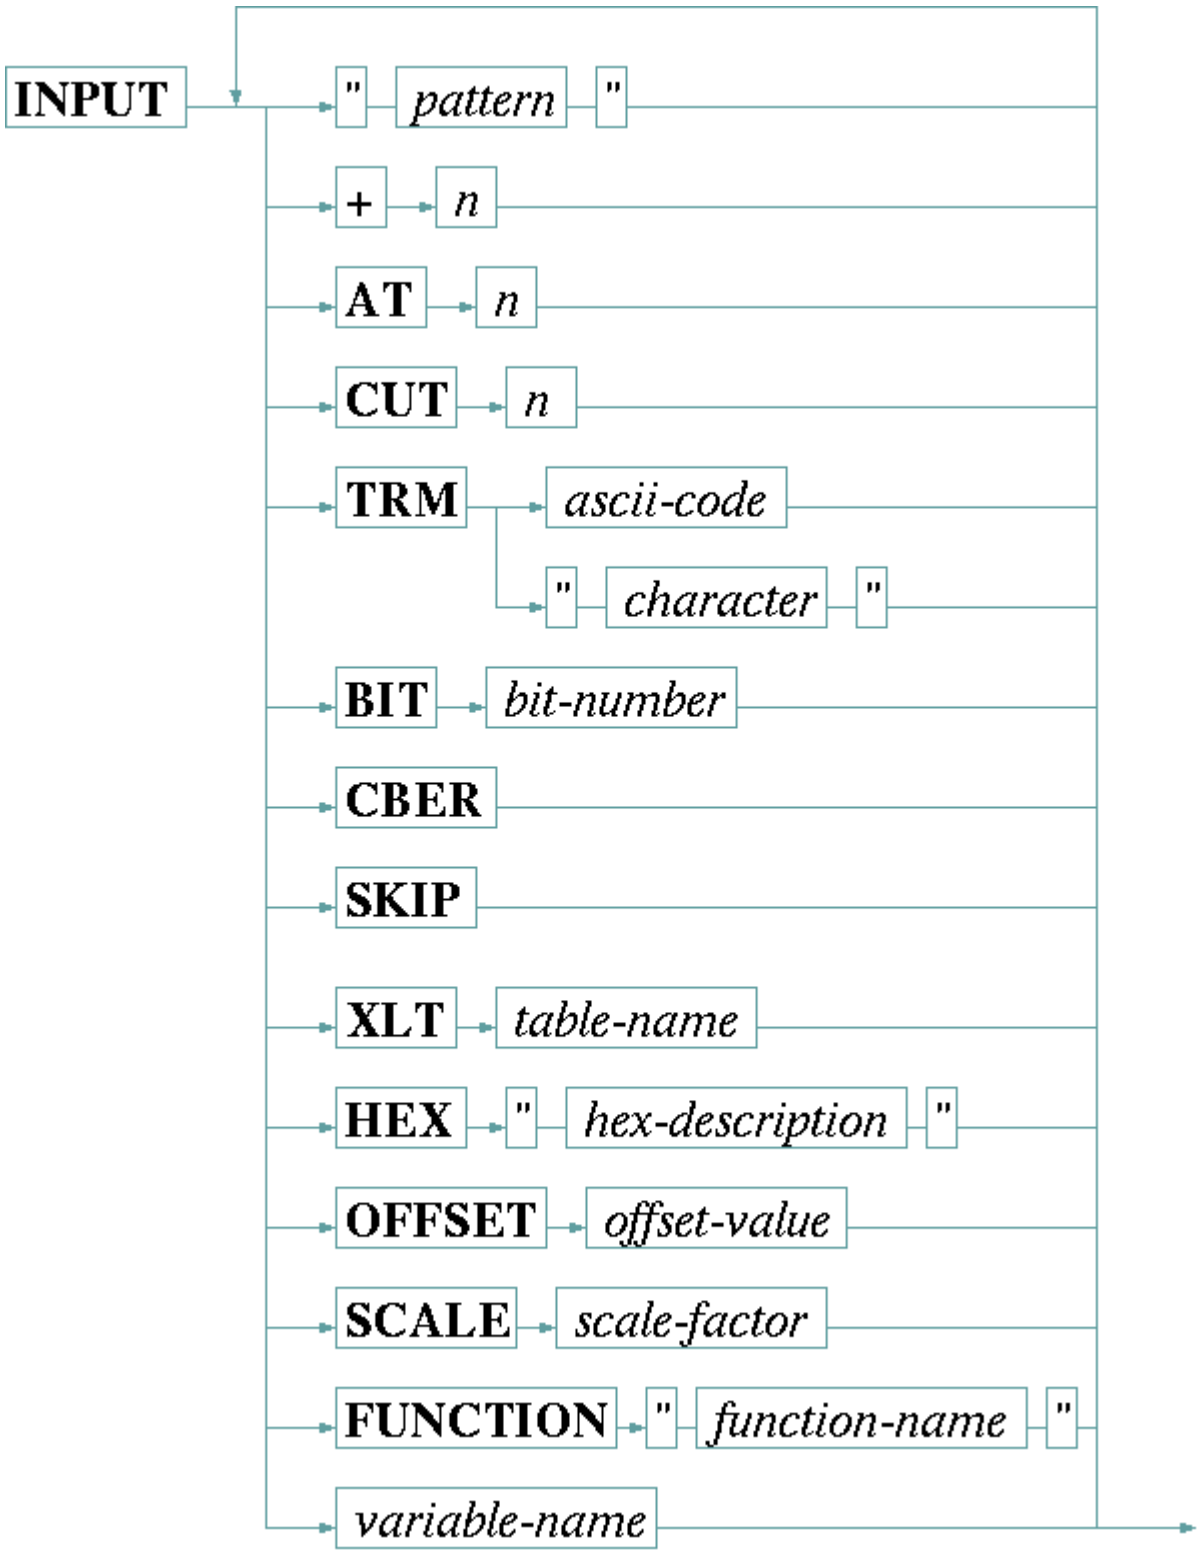
```
PRINT "TUN;FRQ=" SCALE 8.0 FMT "d06" frequency
```

The example above sends a command of the format `TUN;FRQ=######` to the device. The

`FLOAT` variable `frequency` is multiplied by `8.0` and the output as an integer number, 6 digits wide with leading zeroes.

7.2.5.2 The INPUT statement

The `INPUT` statement is used to read and interpret the reply of a device which uses a text based communication protocol. It reads a protocol frame from the device and parses the received message according to the rules defined by the description following the `INPUT` keyword. The syntax of the `INPUT` statement is:



While parsing the device's reply, the driver deals with three information buffers.

1. *original reply*
2. *pad* buffer
3. *value* buffer

To understand the way how the parsing operations work which may follow the `INPUT` keyword, it is necessary to learn how the driver uses these buffers.

- The first buffer contains the original reply string as it is received from the device (with the protocol frame stripped off).
- The driver initially copies this string into a second buffer called *pad*. Search operations (text in double quotes) and the "+" operation modify the *pad*. The AT operation is the only way to restore the *pad* from the original data.
- Every time, the *pad* is modified, the driver copies it's contents into the third buffer called *value*. *Value* is the string which will be assigned to a variable if it appears in the list of arguments to the `INPUT` statement. Operations in the `INPUT` statement like `CUT`, `TRM`, or `XLT` work on the *value* buffer but leave the *pad* unchanged. This is important to understand if you have to parse the value of more than one variable in a single `INPUT` statement.

" pattern "	Searches the text/pattern in the current *pad* buffer. If the pattern is found, all text including the first occurrence of the pattern is removed from the beginning of the *pad* buffer. The pattern text may contain escape sequences like `\n` or `\t` to search for line feeds or tabulator characters.
+ n	Removed `n` characters from the beginning of the *pad* buffer.
AT n	Restores the *pad* buffer with a substring of the original data, starting at column `n`.
CUT n	Cuts the *value* buffer to a length of `n` characters.
TRM "c"	Removes the first occurrence of the termination character and all following text from the *value* buffer. The termination character may be specified as a decimal number (e.g. 10 is the ASCII code for line feed) or as a single character enclosed in double quotes.
BIT n	Interprets the *value* buffer as a decimal number and isolates the bit number `n` (`n = 0` means the least significant bit). The value buffer is replaced by `0` or `1` depending on the bit value.
CBER	Interprets the *value* buffer as a bit error rate value as it is returned by Comstream modems. A string `mn` is converted into the more common notation `mE-n`.
SKIP	Removes any whitespace (space characters, line feeds, carriage returns or tabs) from the beginning of the *value* buffer.
XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the *value* buffer through this translation table from right to left. Chapter Using conversion tables gives more information about tables in general.

OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, interprets the *value* buffer as a floating point number and replaces the buffer with the sum of the value and the offset.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, interprets the *value* buffer as a floating point number and replaces the buffer with the product of the value and the scale factor.
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
variable-name	A variable name tells the driver to assign the contents of the*value* buffer to this variable. The driver performs format conversions and range checks according to the type and limit specifications made in the VAR definition of this variable.
HEX ".."	Interprets the contents of the *value* buffer as a hex number and replaces it by it's decimal equivalent.

The format definition string which must follow the HEX keyword may contain the following characters:

L	The hex number is in *little endian* notation. This means the least significant byte is written at first. If no `L` character is in the format string, *big endian* notation is assumed.
S	The hex number is signed. The number of digits is used to calculate the sign extension: `80` for example is calculated as `-1` as the two digit number is assumed to be a byte value. `0080` in contrast is computed to `128` as a 16 bit number of this value is positive.

Remarks

If a value is not assigned to a variable as you expect, you should check the following issues:

- Numeric values are converted from string to numeric representation in a very lenient way. For instance, any leading non-numeric characters are ignored. If a numeric variable is not assigned as expected, in most cases there is a range violation. The driver does not accept values outside the range defined for this variable.
- `CHOICE` variables and tables (referenced with the XLT operation) expect an input value which *exactly* matches one of the valid choices. See chapterUsing conversion tables to read how you can make tables somewhat fault tolerant.

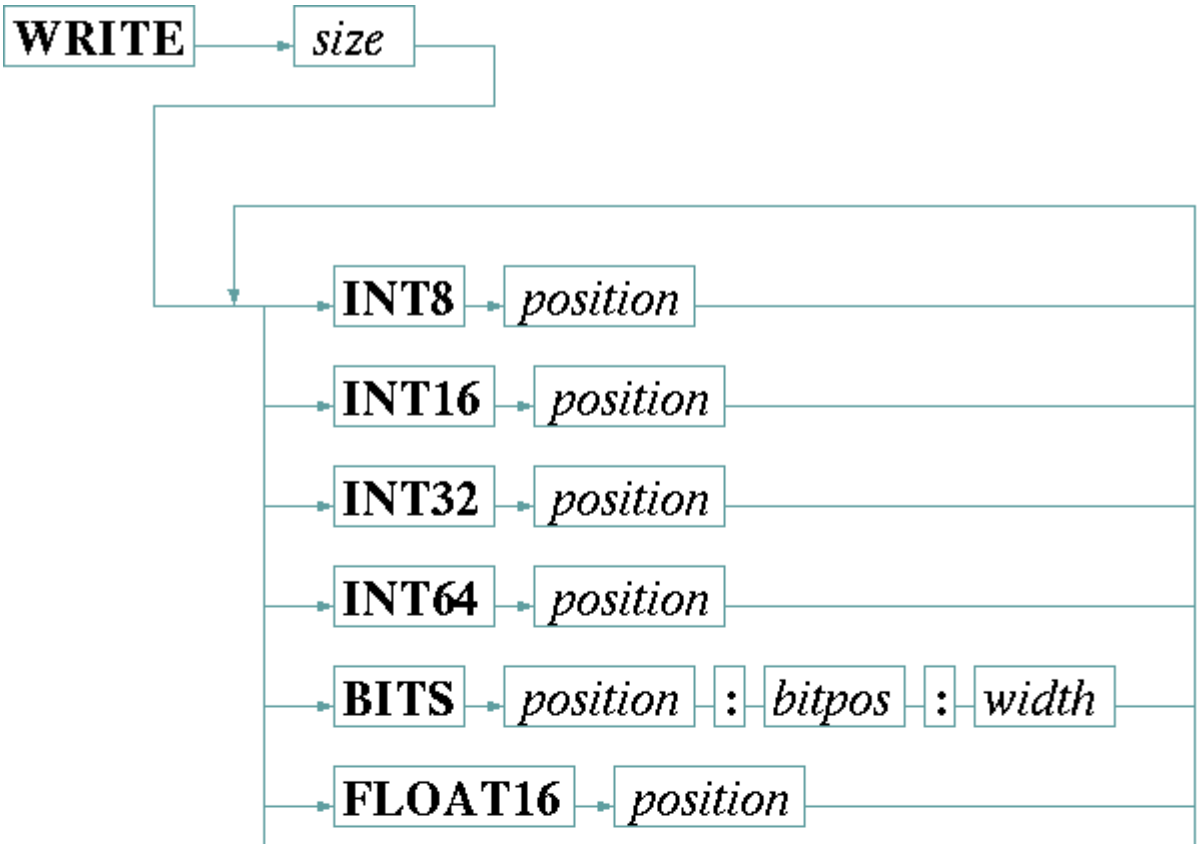
Example

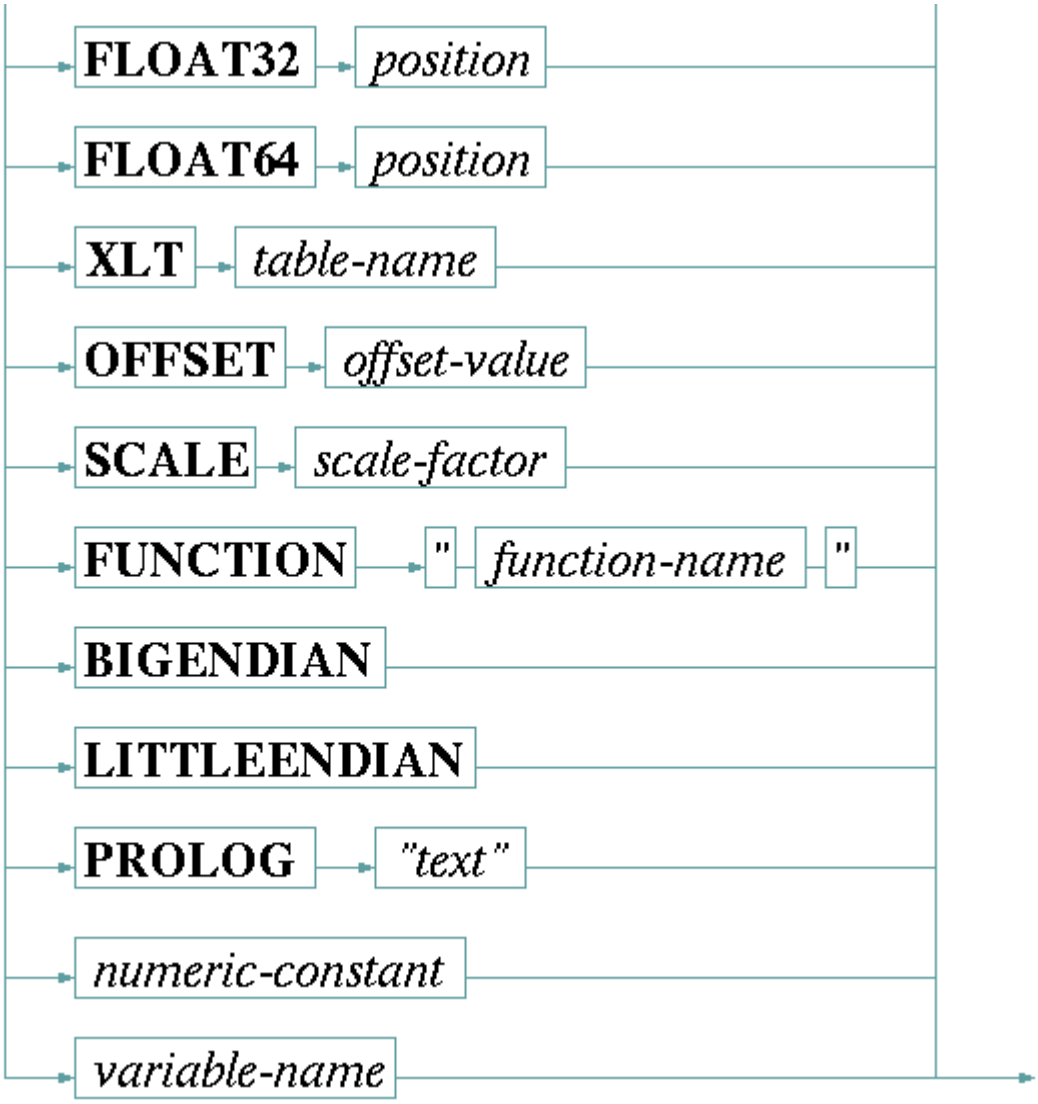
```
INPUT AT 2  SCALE 0.001          tx.frequency
      AT 11 SCALE -0.1 OFFSET 30.0 tx.gain
      AT 15 CUT 1 XLT T03        faults.01
      AT 17 CUT 1 XLT T02        info.if
      AT 19 CUT 1 XLT T01        tx.on
      AT 21 CUT 1                faults.02
      AT 22 CUT 1                faults.03
      AT 23 CUT 1                faults.04
      AT 24 CUT 1                faults.05
      AT 25 CUT 1                faults.06
      AT 26 CUT 1                faults.07
```

The example above - taken from the NDSatCom-KuBand-Upconverter device driver - parses all settings an faults flags from a single status string the upconverter returns. Note that the numeric variables `tx.frequency` and `tx.gain` are isolated from the string without specifying a length or a termination character. The number recognition routine automatically stops where it finds a non-numeric character after the number to read. The other values however all are cut to one character length before they are interpreted.

7.2.5.3 The WRITE statement

The `WRITE` statement is used to send data to the device which uses a binary communication protocol. Such a device expects a command as a binary data structure rather than as a readable text. The syntax of the `WRITE` command is:





The `WRITE` statement creates a buffer of the specified number of bytes which initially is filled with zeroes. Variables or constant values are copied into this buffer according to the size and position specifications given.

The `WRITE` statement by default works in *little endian* mode. 16, 32 or 64 bit values are copied into the buffer with the least significant byte first. Specifying `BIGENDIAN` mode reverses this byte order.

size	The size (number of bytes) of the message buffer to create must be specified as the first argument following the `WRITE` keyword. The size value is expected as a decimal number.
INT8 p	The `INT8` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a single byte value at the given position (position zero denotes the first byte in the buffer).

INT16 p	The `INT16` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a two-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless `BIGENDIAN` was specified.
INT32 p	The `INT32` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a four-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless `BIGENDIAN` was specified.
INT64 p	The `INT64` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a eight-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless `BIGENDIAN` was specified.
BITS p : b : w	The `BITS` keyword tells the driver to place the next value as a 1 to 7 bit wide bit field within a certain byte. In this case the position parameter consists of three values, separated by colons:
	position `p` addresses the byte within the buffer.
	bitpos `b` defines a number of bit positions the value shall be shifted left before it is pasted into the byte.
	width `w` the number of bits (starting with the least significant one) which shall be copied from the next constant or variable into the destination byte.
FLOAT16 p	The `FLOAT16` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a half precision (16 bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless BIGENDIAN was specified.
FLOAT32 p	The `FLOAT32` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a single precision (32 bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless BIGENDIAN was specified.

FLOAT64 p	The `FLOAT64` keyword, followed by a decimal position value, tells the driver that the next constant or variable shall be copied to the buffer as a double precision (64-bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is placed first unless BIGENDIAN was specified.
XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the next variable value which shall be printed through this translation table. When output by a `WRITE` statement, any non-numeric variable must be translated through a table into a numeric value. Chapter Using conversion tables gives more information about tables in general.
OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, tells the driver to add the offset value to the next variable before it is pasted into the buffer.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, tells the driver to multiply the next variable with the scale factor before it is pasted into the buffer.
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
BIGENDIAN	The `BIGENDIAN` keyword turns the byte order from *little endian* (LSB first) which is the default to *big endian* (MSB first). This applies to all values written after BIGENDIAN.
LITTLEENDIAN	The `LITTLEENDIAN` keyword turns the byte order back to *little endian* (LSB first). This applies to all values written after `LITTLEENDIAN`.
PROLOG "text"	The `PROLOG` keyword followed by a quoted string sets this string as a *prolog* to be sent before the binary data specified in the WRITE statement. Actually, this is only usable together with the HTTP11 protocol to generate a HTTP 1.1 POST request. Example: `PROLOG "POST some/url "` prepends this text before the binary data.
numeric-constant	Numeric (decimal) constants can be used like variable names. The constant value is pasted into the output buffer in this case. If a quoted string is given, this is treated as a hexadecimal constant and translated into a numeric value.

variable-name	A variable name tells the driver to paste the value stored in this variable into the output buffer according to the size and position specification given before. Usually the *commanded* value is used rather than the value which has been read back from the device. If, however, there has been never a value commanded, or if this variable is a read only variable, the value recently read from the device is used.

Before the variable is printed to the output buffer, any `XLT` , OFFSET `or` SCALE` operations which have been specified are applied. This happens in a fixed order:

1. If a `SCALE` operation has been specified, this is done first.
2. The `SCALE` operation is followed by an `OFFSET` addition.
3. The so scaled value is processed through a `FUNCTION` if there is one.
4. The processed value is formatted according to a `FMT` specification if one is given.
5. Finally, the value gets translated through a translation table, if an `XLT` operation has been specified.

Remarks

- Each variable name or constant must be preceded by an `INT8` , `INT16` , `INT32` , `INT64` or `BITS` specification to be pasted properly into the output buffer.
- Only `INTEGER` , `HEX` or `FLOAT` type variables can be used directly with the `WRITE` statement. For other variable types an `XLT` table translation must be used to turn the variable into a numeric value.
- `FLOAT` variables are converted to 64-bit integer values before they are used. `OFFSET` or `SCALE` operations are done before this conversion.

Example

```
TABLE T02 "QPSK=0,BPSK=1"

...

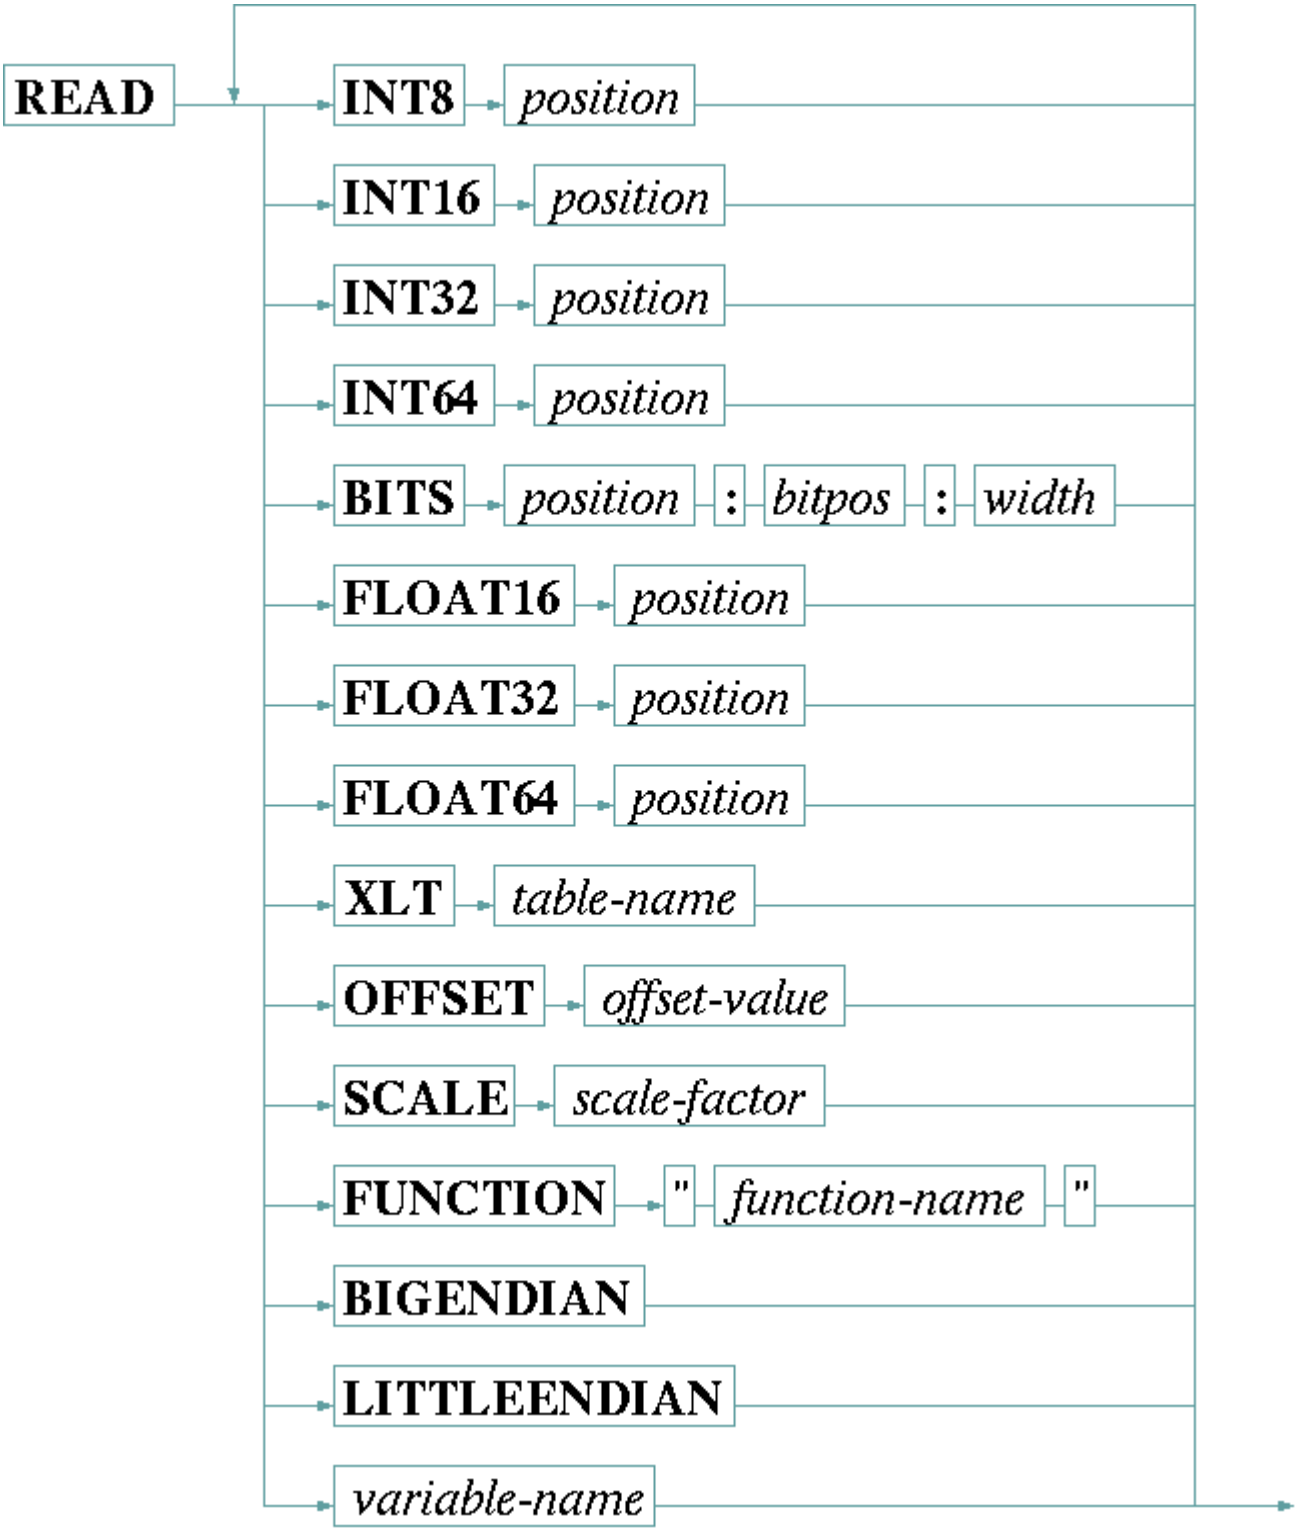
WRITE 3 BIGENDIAN
   INT16 0  9734
   INT8  2  XLT T02        tx.mod.type
```

The example above -- taken from the Radyne DVB3030 modulator driver -- explains how to write a `CHOICE` parameter to a device. Table `T02` is used to convert the QPSK/BPSK selection into the numeric values 0/1. The WRITE statement sends a message (three bytes long plus protocol frame overhead) in *big endian* byte order. The first two bytes are filled with the decimal constant `9734` (a command code). The third byte is set to `0` or `1` according to the contents of `tx.mod.type` .

7.2.5.4 The READ statement

Receiving and interpreting of data returned from devices which use a binary communication

protocol is done with the `READ` statement. The `READ` statement gets a message from the device, strips off the protocol frame and places the result in an internal buffer. Subcommands/operations following the `READ` keyword are used to copy values from the buffer into one or more variables of the device driver.



The `READ` statement by default works in 'little endian' mode. 16, 32 or 64 bit values are read

from the buffer with the least significant byte first. Specifying `BIGENDIAN` mode reverses this byte order.

INT8 p	The `INT8` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a single byte value at the given position (position zero denotes the first byte in the buffer).
INT16 p	The `INT16` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a two-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless `BIGENDIAN` was specified.
INT32 p	The `INT32` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a four-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless `BIGENDIAN` was specified.
INT64 p	The `INT64` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a eight-byte value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless `BIGENDIAN` was specified.
BITS p : b : w	The `BITS` keyword tells the driver to read a 1 to 7 bit wide bit field from a certain byte in the buffer. In this case the position parameter consists of three values, separated by colons:
	position `p` addresses the byte within the buffer,
	bitpos `b` defines the bit-number (0 to 7) of the least significant bit to read.
	width `w` the number of bits which shall be copied from the buffer into the destination variable.
FLOAT16 p	The `FLOAT16` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a half precision (16 bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless BIGENDIAN was specified.

FLOAT32 p	The `FLOAT32` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a single precision (32 bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless BIGENDIAN was specified.
FLOAT64 p	The `FLOAT64` keyword, followed by a decimal position value, tells the driver that the next variable appearing in the argument list shall be filled from a double precision (32 bit) IEEE754 floating point value starting at the given position (position zero denotes the first byte in the buffer). The least significant byte of the number is read first unless BIGENDIAN was specified.
XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the value read through this translation table from right to left. Chapter Using conversion tables gives more information about tables in general.
OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, tells the driver to add the given offset to the value read.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, tells the driver to multiply value read with the given factor.
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
BIGENDIAN	The `BIGENDIAN` keyword turns the byte order from *little endian* (LSB first) which is the default to *big endian* (MSB first). This applies to all values read after BIGENDIAN.
LITTLEENDIAN	The `LITTLEENDIAN` keyword turns the byte order back to 'little endian' (LSB first). This applies to all values read after `LITTLEENDIAN`.
variable-name	A variable name tells the driver to store the value read into the variable.

Example

```
READ BIGENDIAN
   INT32 1  SCALE 0.000001   tx.frequency
   INT32 7                   tx.mod.dataRate
   INT32 11 SCALE 0.000001   refClkFreq
   INT8  15 XLT T01          refClkSrc
   INT8  16 XLT T02          tx.mod.type
   INT8  17 XLT T03          tx.mod.fec
   INT16 22 SCALE 0.1          tx.power
   INT8  24 XLT T04          tx.on
   INT8  24 XLT T04          internal.tx.on
   INT8  25 XLT T05          tx.mod.cwMode
   INT8  26 XLT T06          tx.mod.spectrumInvert
   INT8  28 XLT T14          tx.ifc.hardware
   INT8  29 XLT T06          tx.ifc.clockPhase
   INT8  30 XLT T06          tx.ifc.dataPhase
   INT8  31 XLT T07          tx.mod.clockSource
   INT8  44 XLT T08          info.maskEnable
   INT32 45                  info.alarmMask
   INT32 49                  tx.mod.symbolRate
   INT8  53 XLT T09          tx.ifc.framingMode
   INT8  54 XLT T10          tx.mod.rollOff
   INT8  55 XLT T11          config.control
   INT8  57 XLT T12          modemType
```

The example above - taken from the Radyne DVB3030 modulator driver - shows the main settings `READ` statement of this driver. In one step almost all parameter settings are read.

7.2.5.5 Function tables in I/O functions

The I/O functions of the ***sat-nms*** driver language (`INPUT` , `PRINT` , `READ` , `WRITE` and the REST I/O functions) all provide with the `FUNCTION` keyword a feature to translate a numeric value along a table of x/y value pairs. The result of the function is calculated by linear interpolation in this table.

File format

A `FUNCTION` requires the table of x/y values to be stored as a simple text file which looks like the following example:

```
# function table, defines a square root function

0.0   0.0
1.0   1.0
4.0   2.0
9.0   3.0
16.0   4.0
25.0   5.0
```

The table consists of two or more lines, each consisting of the x-value followed by one or more space characters and the corresponding y-value. Both values must be valid floating point numbers. Blanc lines and lines starting with a `#` character are ignored.

The x-values need no to be e equally spaced, but the values must be sorted in ascending order, starting with the lowest one.

Calculation method

The function calculates the the y-value to a given x-value by linear interpolation. This means, the curve defined by the x/y pairs is a polygonal line. The table should contain enough x/y-pairs to meet the expected accuracy of the function.

For x-values outside the range of x/y pairs defined in the table, the function extrapolates the y-value using the slope given by the outmost two x/y pairs. You may want to set two additional x/y-pairs outside the real table to set this slope to a particular value.

File name processing

When executed in an I/O statement, the function extends the function name defined in the driver to the name of the file containing the function table. First the letters `.txt` are appended to the function name. The `.txt` file extension makes it easy to open the file with a text editor from the file manager of any operating system. Function table must be placed in the base directory of the ***sat-nms*** installation (usually `/home/satnms/`).

If the function name starts with a `-` character, the name of the device is prepended to the function name. For example, a function name `"-caltable"` would expand to a file name `DEVNAME-caltable.txt` where `DEVNAME` is the name of the actual device. This is useful for e.g. calibration tables which are different for each particular device.

Error handling

The function checks if the file for this function exists. The driver raises a communcation fault if a `FUNCTION` clause with non-existing file is processed. If the file itself cannot be parsed for some reason, the function tries to do its best, recovering from this situation if possible. A note is written to the `.panic.log` file, if such an error occurs.

7.2.6 REST I/O functions

Beside the basic I/O functions described in the previous chapters, the***sat-nms*** driver definition

language provides some statements to handle the communication with devices using a REST API in an efficient way.

The REST API transports settings and status information as structured, JSON-formatted documents over an HTTP protocol. JSON documents are plain text and therefore may be - at least principally - handled by the basic PRINT / INPUT statements. In practice however, parsing a JSON document with the capabilities of INPUT may become difficult and in the end will result in a device driver which is hard to understand and to maintain.

The REST I/O statements contained in the ***sat-nms*** driver definition language take care of the special structure and formatting of JSON documents, helping to focus on the content to send or retrieve rather than the special JSON syntax. The statements for REST communication are:

REST TRANSACT	Sends a REST HTTP request to the device, for HTTP `POST` , `PUT` or `PATCH` with a JSON formatted document body attached. Retrieves the device's reply and parses the document body into an object tree.
REST PARSE	Accesses the objects contained in the most recent reply from the device and assigns the object values to ***sat-nms*** driver variables.
REST SET	Modifies the objects contained in the JSON document or adds new objects to it. Used to prepare a document to be sent to the device with one of the `POST` , `PUT` or `PATCH` HTTP methods.
REST CLEAR	Clears the JSON document in memory. This function is used to prepare a document from scratch for a `POST` or `PATCH` call.
REST SEND	takes the actual JSON document and sends it to the device. It is used with protocols other than HTTP and replaces `REST TRANSACT` there.

Object model

A JSON document is a hierarchically structured collection of key / value pairs. The value in such a pair may be either a constant value, another ancillary collection or an array of these. The object model used in the ***sat-nms*** REST I/O functions flatens this tree-like structure, treats every constant value with its key as an object. The key of this constant value is extended to contain the complete information where in the document this key / value pair is located.

Object paths

This location information can be thought as a path from the document's root down to the definition of the constant value of interest. This path is much like a path in a computer's file system. The higher-order nodes in the document tree are like directories in the file system. For this reason, the ***sat-nms*** driver definition language uses a notation like used with file names to identify an object in the document tree:

```
/settings/modulator/datarate
```

for example denotes an object `datarate` contained in the `modulator` branch of the

document which in turn is expected to be contained in the `settings` branch. The JSON equivalent of this would look like this:

```
{
 "settings": {
  "modulator": {
    "datarate": 2048000;
  };
 };
}
```

As with file names and paths, a path identifying an object may be absolute or relative. The example above uses an absolute path to the object: it starts with a slash character. When you access `/settings/modulator/datarate`, the software makes an implicit *change directory* to `/settings/modulator`. If you access then an object named for example `fec`, the software automatically will expand the object name to `/settings/modulator/fec`. This works inside a single `REST SET` or `REST PARSE` statement, not across separate statements.

Object arrays

The array construct in a JSON document works in a special way and therefore needs some special treatment in the ***sat-nms*** driver definition language. JSON arrays are a collection of equally structured nodes. In most REST APIs, the elements of such a collection are not identified by their location in in the collection but by some unique identifier which appears as a regular key / value pair in each element of the array.

To cope with this construct, the ***sat-nms*** driver definition language exteds the object path definition with "conditions" used to identify a particular collection element:

```
/settings/modulator/output[id=3]/enable
```

addresses the `enable` object in that `output` branch that has a key `id` set to `3`. Conditions may appear after each branch name in the object path. There may be multiple conditions which are combined with a logical **and**:

```
/settings/modulator/connector[number=2][type=OUTPUT]/enable
```

addresses the `enable` object in that `connector` branch that has a key `number` set to `3` **and** `type` set to `OUTPUT`.

Alternatively, array elements may be addressed by their position in the array. The numeric array index starts with `0` for the first array element:

```
/settings/modulator/output[2]/enable
```

addresses the `enable` object in the third (index=2) 'output' branch. Please note, that this only works, if the API of the device to control explicitly permits to access array elements by position.

Furthermore it is not possible to create array elements by position index in the REST SET statement.

Document handling

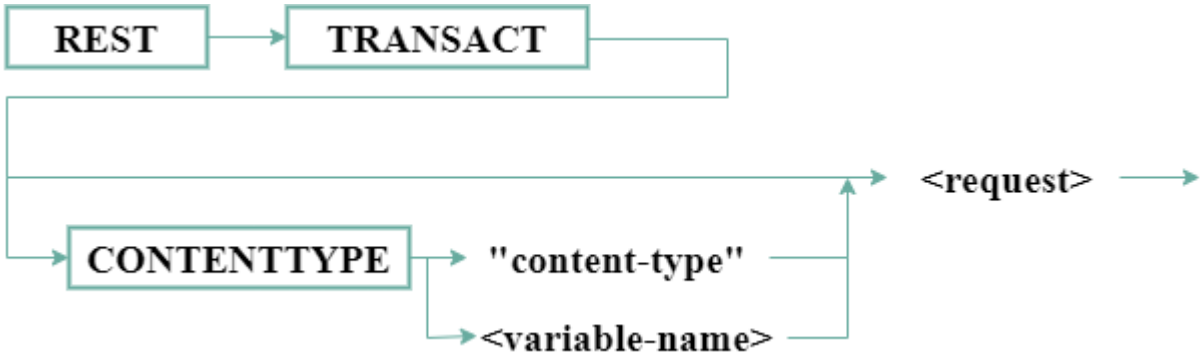
With the REST statements in the ***sat-nms*** driver definition language there is always one JSON document in memory these statements work on. Generally, it is the REST TRANSACT statement which creates this document from the device's reply, REST CLEAR creates an empty document instead. The REST SET statement can be used to add or modify objects in the document, the REST PARSE statement to query objects from there.

With a REST TRANSACT doing a HTTP GET command you can expect to get the information you addressed in the GET command, but POST, PUT or PATCH also may return a document containing some information that might be important for the device driver.

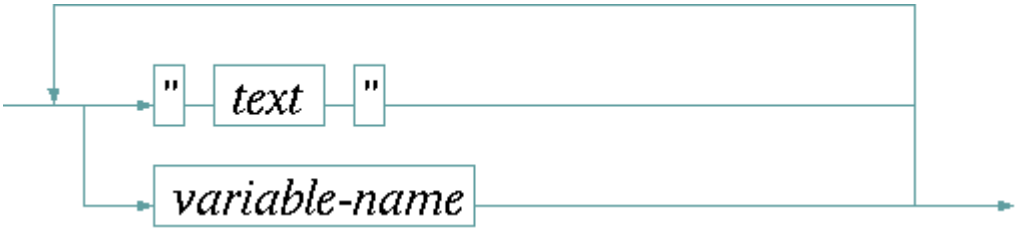
When issuing a POST, PUT or PATCH command, the REST TRANSACT statement sends the existing document to the device using the selected HTTP method, then replaces the document by the parsed reply from the device.

7.2.6.1 The REST TRANSACT statement

The REST TRANSACT statement sends a REST HTTP request to the device, either with or without a JSON formatted document body. It retrieves the device's reply and parses the document body into an object tree.



The request is an arbitrary long sequence of quoted strings and ***sat-nms*** variables. Strings and variable content are concatenated to build the request string:



The request must start with the HTTP method to execute (one of GET, PUT, POST, PATCH or DELETE), followed by one space character and the path of the URL to read. The path may contain URL parameters. Example:

```
GET /api/v1/settings/modulator?slot=2
```

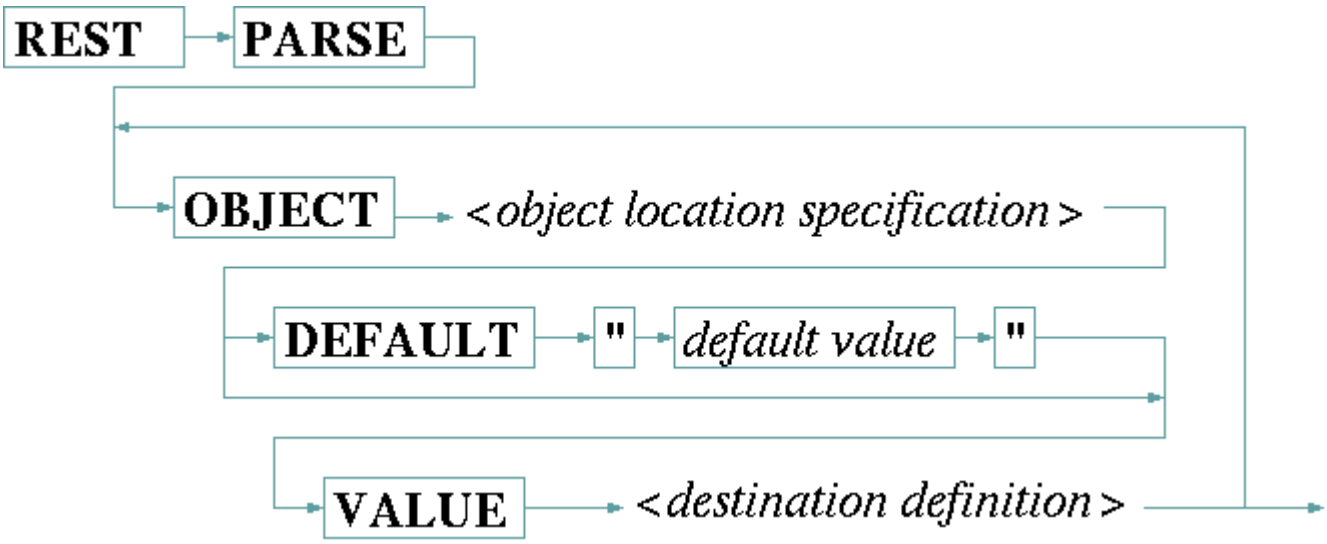
Please note, that no URL-encoding is done on this string, this means that all special character must be escaped (e.g. blanc replaced by '+')

With the POST, PUT or PATCH HTTP methods, REST TRANSACT sends the JSON document actually in memory to the device. This document may be created from scratch or the recent reply from the device may be used as a template which is modified before the transaction is executed. To transact a HTTP method other than GET without sending a JSON document, place a REST CLEAR statement directly above the REST TRANSACT.

REST TRANSACT may be immediately followed by the keyword CONTENTTYPE and a content type definition in double quotes or contained in a variable. This content type definition overrides any PROTOCOLPARAMETER post.content.type=... definition made in the protocol or driver header.

7.2.6.2 The REST PARSE statement

The REST PARSE statement accesses the objects contained in the most recent reply from the device and assigns the object values to ***sat-nms*** driver variables. It uses the same object model as described above for the REST TRANSACT statement to address and extract the desired information from the JSON document the device replied through its REST API.

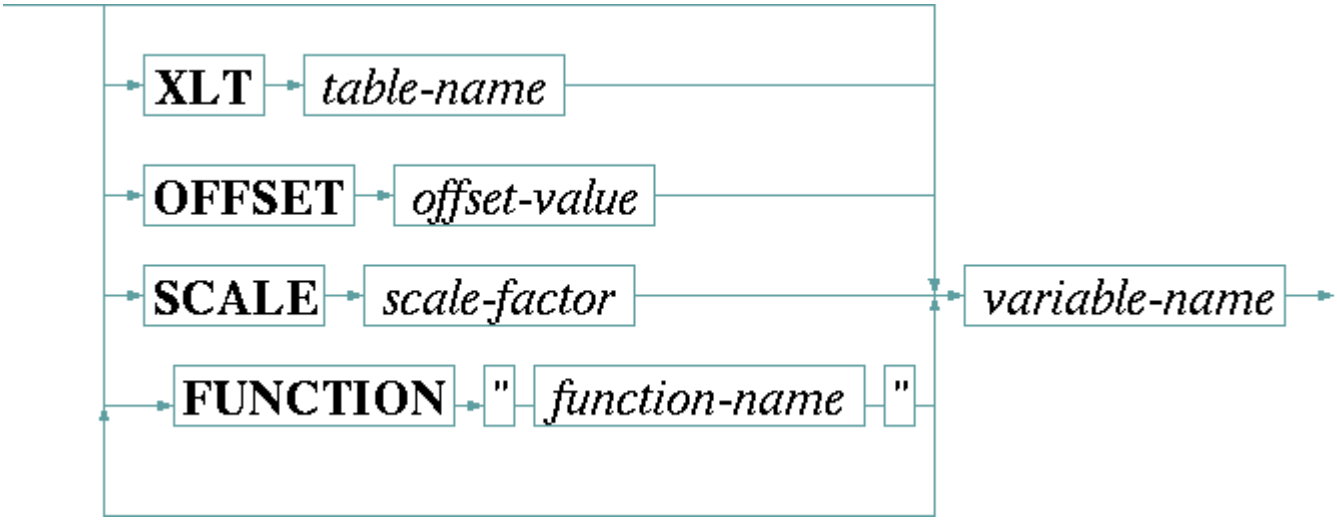


The OBJECT keyword followed by the object location specification addresses the object in the JSON tree to be read. The object location specification works exactly as described above with one difference: non-existent objects are not created but treated as a fault unless there is a default value defined for this object.

The optional DEFAULT keyword denotes the default value to be assigned if the specified object does not exist in the object tree. The default value is given as a quoted string following the DEFAULT keyword. Please note, this value is treated as value read from the JSON document, it undergoes the modifications like XLT, SCALE or OFFSET following VALUE

before it is assigned to the ***sat-nms*** driver variable. If no `DEFAULT` is defined within an `OBJECT` clause and the addressed object is missing in the JSON document, the driver will raise a communication fault.

The keyword `VALUE` starts the definition of the ***sat-nms*** driver variable which shall receive the extracted value together with some modifiers known from the `INPUT` statement. The destination definition in any case ends with then name of the ***sat-nms*** driver variable which may be prepended by zero or more of the modifiers `XLT`, `OFFSET` or `SCALE` as shown below:



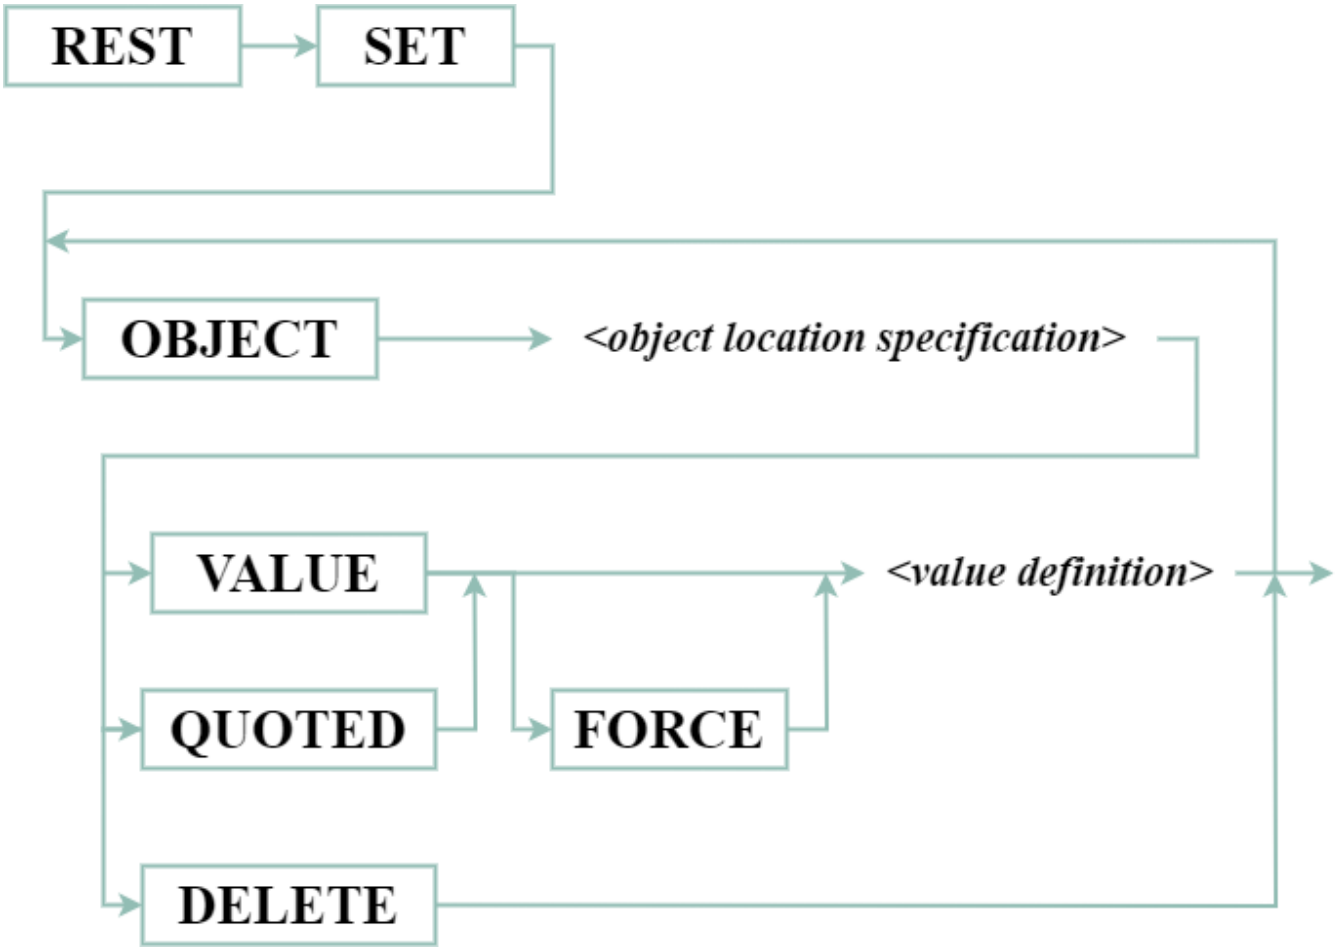
XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the object's value through this translation table from right to left. Chapter Using conversion tables gives more information about tables in general.
OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, interprets the object's value as a floating point number and replaces it with the sum of the value and the offset.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, interprets the object's value as a floating point number and replaces it with the product of the value and the scale factor.
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.

If there are multiple driver variables to be read from a single REST reply sent by the device, you may either use separate `REST PARSE` statements for this or use a single statement with multiple `OBJECT` clauses. Example

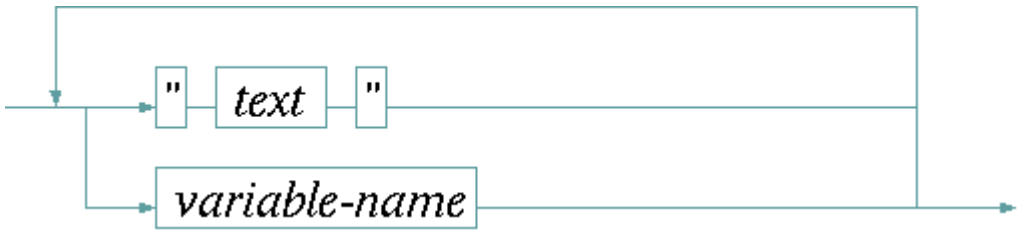
```
REST TRANSACT "GET /api/v1/modulators"
REST PARSE
  OBJECT "/settings/modulator[slot=" config.slotNo "]/frequency"
    DEFAULT "1500.000" VALUE tx.frequency
  OBJECT "/settings/modulator[slot=" config.slotNo "]/fec"
    DEFAULT "3_4" VALUE XLT tFec tx.fec
```

7.2.6.3 The REST SET statement

The `REST SET` statement modified objects in the actual JSON document tree or adds new key / value pairs to the document. The statement starts with the REST SET keywords followed by one or more `OBJECT ... VALUE or OBJECT ... QUOTED` clauses:

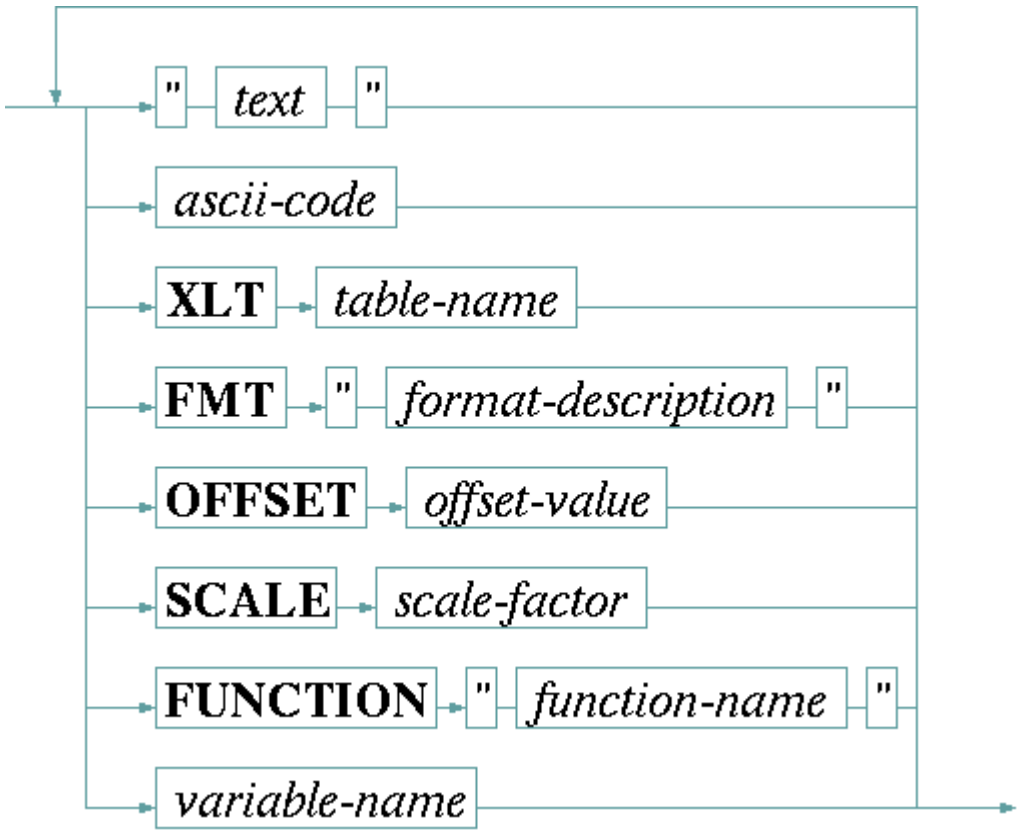


Each object definition starts with the `OBJECT` keyword, followed by the object location definition. The object location definition may be concatenated from multiple quoted strings and ***sat-nms*** driver variables. Section *object paths* in chapter REST I/O functions describes object location definitions more detailed.



Within the REST SET statement, each object is newly created with all its parent objects if it does not yet exist in the document. This includes *conditional* definitions for array elements. If an object already exists in the document, its value will be overwritten by the value specified later in this OBJECT clause.

The object location definition is terminated by the VALUE keyword which starts the definition of the value which shall be assigned to this object. Alternatively, QUOTED may be used instead of VALUE, this is used for textual values which shall be enclosed in double quotes in the JSON text.



The value definition itself is much like writing a command using the PRINT command:

"text"	Plain text, enclosed in double quotes, is added to the output buffer as it is.
ascii-code	A decimal number is interpreted as the ASCII code of a single character to output. You may use this to send special characters like carriage-return or line-feed to the device.

XLT table	The `XLT` keyword, followed by the name of an already defined table, tells the driver to translate the next variable value which shall be printed through this translation table. Chapter Using conversion tables gives more information about tables in general.
FMT "..."	The `FMT` keyword, followed by a format description in double quotes, tells the device driver to format the next variable following the format description given. `FMT` is used to format numeric variables into the representation the device expects in it's remote control command.

A format description consists of the following elements:

format character	description
d b x X f	The first letter of the format description defines the general number representation: `d` (decimal), `b` (binary), `x` (hex, lower case), `X` (hex, upper case) or `f` (floating point)
+	If the `+` option is given, the number is preceded by a +/- character even if it is positive. Together with the `0` option below, the sign appears as an additional character at the first column, hence the field width is increased by one on this case.
0	If the `0` option is given, the field is padded up with zeroes instead of spaces.
1 .. 99	Here follows a one or two digit field width. The field width is the total number of characters the formatted number occupies including the padding characters. If there are more digits needed to show a number correctly, the field with is enlarged automatically. Specifying a field width `1` disables the right orientation in a fixed width completely. This specially is useful for floating point numbers where only the number of fraction digits shall be fixed, not the complete field width.
.	For floating point formats the dot separates the precision from the field width.
0 .. 9	The dot is followed by a one digit specification of the number of fraction digits which shall be printed. The dot and fraction digits specification is valid only with the floating point format.

`INTEGER` variables may be printed using a floating point format, and `FLOAT` variables may be printed with a `d` or `x` format likewise. With `FLOAT` variables you should format in any case as internal precision/rounding problems may cause unpredictable results when floating point values are printed unformatted.

OFFSET o	The `OFFSET` keyword, followed by the (floating point) offset value, tells the driver to add the offset value to the next variable before it is printed.
SCALE s	The `SCALE` keyword, followed by the (floating point) scale factor, tells the driver to multiply the next variable with the scale factor before it is printed
FUNCTION "name"	The `FUNCTION` keyword, followed by the name of the function as a quoted string, tells the driver to apply this function to the next variable before it is printed. The function name is extended by appending `.txt` to achieve the file name to read for the function definition. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
variable-name	A variable name tells the driver to print the value stored in this variable. Usually the *commanded* value is used rather than the value which has been read back from the device. If, however, there has been never a value commanded, or if this variable is a read only variable, the value recently read from the device is used.

Before the variable is printed to the output buffer, any `XLT`, `FMT`, `OFFSET` or `SCALE` operations which have been specified are applied. This happens in a fixed order:

1. If a `SCALE` operation has been specified, this is done first.
2. The `SCALE` operation is followed by an `OFFSET` addition.
3. The so scaled value is formatted according to a FMT specification if one is given.
4. Finally, the value gets translated through a translation table, if an `XLT` operation has been specified.

This scheme applies to numeric (`INTEGER`, `HEX`, `FLOAT`) and to text type variables as well. As soon as a `SCALE`, `OFFSET` or `FMT` keyword is present in front of a variable, this gets converted to a floating point number. Strings which cannot be converted give a zero value.

Example

```
REST CLEAR
  REST SET OBJECT "/settings/frequency" VALUE FMT "f1.3" tx.frequency
  REST SET OBJECT "/settings/fec" QUOTED XLT "tFec" tx.fec
TRANSACT "PATCH /api/v1/modulators?slot=2"
```

Value quoting

In JSON, textual values are enclosed in double quotes, numeric and boolean values are not. The ***sat-nms*** Software does this automatically by looking at the value to set if this is a boolean, a number or a text. This may fail, if the device expects a number enclosed in double quotes.

To cope with this, the `REST SET` statement lets you force the usage of quotes in several ways:

1. Enclose the value in quotes when sending it. You may use single quotes instead of double quotes to avoid the need of escaping the double quote with a backslash. The JSON document sent to the device will contain double quotes instead of the single ones used in the driver. With constraint definitions in the object path this is the only way to force quotes if required.
2. For the value set in a JSON object, you may use the `QUOTED` keyword instead if `VALUE`. The value will be forced to be set in double quotes when added to the document. This way produces better readable code than putting the quote characters explicitly in the sequence of operands after `VALUE`.

Conditional execution

By default a `VALUE` or `QUOTED` clause in the `REST SET` statement causes the JSON document only to be modified if

- The value to be set is a constant
- The variable to be set is marked as *to be written* by the driver. This is if the driver was commanded to set this value, but this did not yet happen.

This behavior protects the JSON document content from unwanted changes if e.g. only one parameter shall be changed but the `REST SET` statement contains the `OBJECT` .. `VALUE` pairs of all parameters in this group.

You can force values to be written regardless of the conditions described above by introducing the keyword `FORCE` directly after the `VALUE` or `QUOTED` keywords.

Object deletion

When used with `DELETE`, `REST SET` deletes the JSON object specified in the `OBJECT` clause and all of it's child objects.

Parent objects are removed as well if they become empty after deletion of the specified object. Please note, that array elements may still not be empty - even if all known child elements of the array element have been deleted. In this case the array element is not automatically removed, must be deleted explicitly by another `REST SET ... DELETE` statement.

7.2.6.4 The REST CLEAR statement

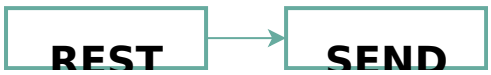
The `REST CLEAR` statement creates an empty JSON document im memory, which deletes the document left by the recent REST TRANSACT statement.

`REST CLEAR` is commonly used to prepare a JSON document from scratch with the `POST` or `PATCH` HTTP methods.

7.2.6.5 The REST SEND statement

The `REST SEND` statement takes the actual JSON document and sends it to the device. It is

used with protocols other than HTTP and replaces `REST TRANSACT` there.

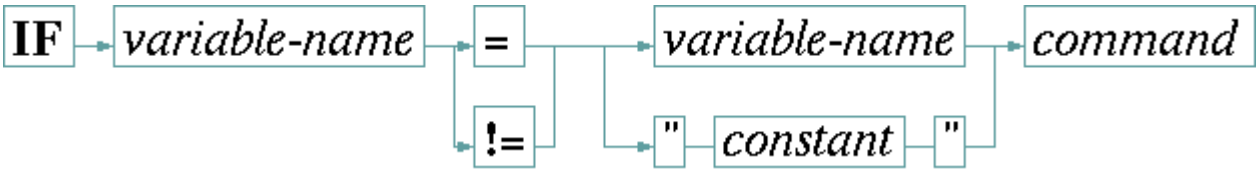


7.2.7 Conditional execution

The device driver language defines a couple of statements to control the flow of execution within a procedure. There is an IF statement as well as a GOTO which refers to a label placed elsewhere in the procedure.

7.2.7.1 The IF statement

The `IF` statement conditionally executes a single statement if the comparison following the `IF` keyword is true.



The keyword `IF` is followed by a comparison of a variable to another variable or constant. With the `=` operator the command is executed if the compared values match, with `!=` if they don't match respectively. Please note, that a constant value must be enclosed in double quotes, even if it is a numeric value. `IF` compares the string representation of the variables after formatting them as defined in the `VAR` statement. Hence, floating point variables always are compared after being rounded to the number of digits defined for the user interface display.

Example

```
IF info.version = "2.0" PRINT "TFR " FMT "f1.3" tx.frequency
IF info.version != "2.0" PRINT "TFR " FMT "d08" SCALE 1000.0 tx.frequency
```

Depending on the value of the `info.version` variable, the example above uses different commands to set the `tx.frequency` at the device. `PRINT` is considered as a single command, with all it's parameters in this case. If more than one command in sequence shall be executed conditionally, a GOTO statement must be used to jump over the this command sequence.

7.2.7.2 The GOTO statement

The `GOTO` statement branches to another location in the same procedure. The destination where to branch to is referenced by a label . The `GOTO` statement lets the execution of the procedure continue at the statement following the label.

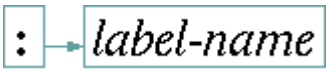
The label, the `GOTO` statement refers to may be defined above or below the location of the `GOTO` statement. However, the label must be defined in the same procedure. The device driver interpreter does not support branches across procedure boundaries.

Some words about loops

Principally `GOTO` statements may be used to create loops within a procedure. You are strongly discouraged from doing so. This is because all procedures for a device (more exactly spoken the procedures of all devices operated at the same physical interface) are executed sequentially. If now one procedure is caught in a loop for some time or perhaps forever, no other procedures will run. The device driver will appear to be *frozen*.

7.2.7.3 Label definition

Labels are defined as destination locations for the GOTO statement. The colon, followed by a label name defines a label:



Labels only are visible within the procedure where they are defined. As a consequence, you may define labels with the same name in different procedures. Within one procedure however, a label name may be used only once. Between the colon and the label name no whitespace is required.

Example

```
IF info.version = "2.0" GOTO v2stuff
   PRINT "TFR " FMT "d08" SCALE 1000.0 tx.frequency
   GOTO finished
:v2stuff
   PRINT "TFR " FMT "f1.3" tx.frequency
:finished
```

7.2.8 Using subroutines

Procedures may be defined to act as subroutines (see chapter The PROC statement for the syntax description). They are not bound to variables in this case. The CALL statement is used to invoke a subroutine from another procedure.

Subroutines are suitable to code operations which have to be done in the same way in several procedures. A common application for this is the check of the device's reply to a command. A subroutine can read the device's reply, check if it is OK and raise a fault flag if not. After a procedure sends a command to the device, it calls the subroutine which does the check.

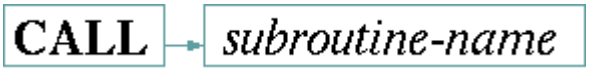
When using subroutines, you should notice the following:

- Subroutines may be nested, this means a subroutine may contain a CALL statement to another subroutine.

- Subroutines must be defined before they can be referenced in another procedure.
- The device driver language allows to define recursive subroutines (subroutines which call themselves). You are strongly discouraged to program recursive subroutines as a program bug in your device driver may cause infinite recursion which definitely will crash the whole MNC application!

7.2.8.1 The CALL statement

The `CALL` statement is used to invoke a subroutine from another procedure. The called routine must be defined before it can be called.



The driver executes all statements of the called procedure and then resumes

Examples

The example below, taken from the Tandberg-Alteia device driver, shows a common application of a subroutine. The subroutine `getAck` is called every time the driver sent a command to the IRD to check if the unit accepted the command.

```
// called after sending a command to the IRD. checks the ACK response which is
// expected.
//
PROC SUBROUTINE getAck
   INPUT "=" TRM "_" internal.ack
   IF internal.ack = "ACK" GOTO endif
      SET faults.commstat = "ACK expected"
      SET faults.99 = "true"
   :endif
```

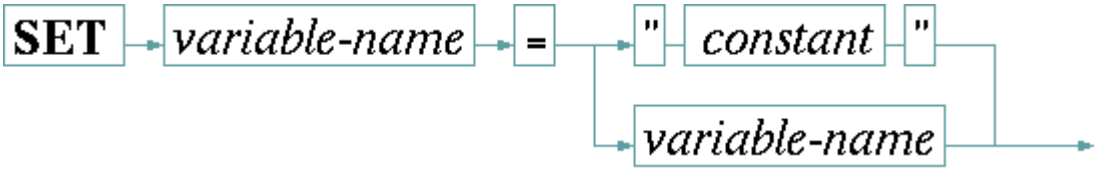
7.2.9 Manipulating variables

The ***sat-nms*** device driver definition language provides a number statements to manipulate driver variables within procedures. These are:

SET	Assigns a value to a variable.
BITSET	Extracts a single bit from a variable and assigns it to another.
RANGESET	Changes the range definition of a variable.
BITSPLIT	Splits up a variable in single bits. Should no longer be used.
BITMERGE	Merges several variables each containing one bit to another variable. Should no longer be used.

7.2.9.1 The SET statement

The `SET` statement lets you assign a value to a variable. The value may be a constant in double quotes (even numeric values must be quoted) or the contents of another variable.



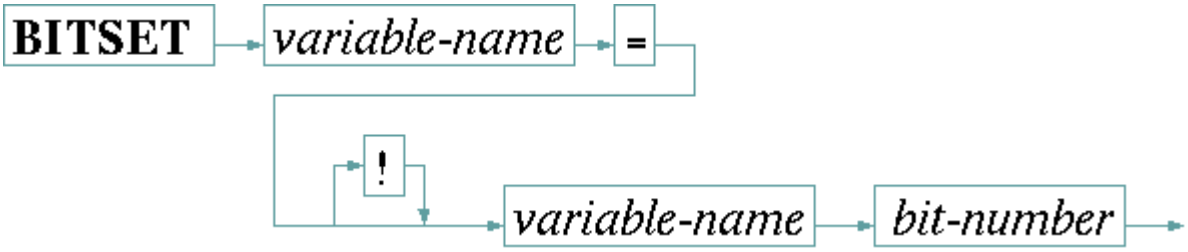
`SET` assigns the value to the internal memory in the variable which remembers the value read from the device. Assigning a value with set hence has the same effect as assigning it within a INPUT or READ statement. `SET` does not change the commanded value a variable receives from the user interface.

Example

```
SET tx.power = "33.2"
```

7.2.9.2 The BITSET statement

Some devices report their fault state as a number in which each bit represents one fault flag. The `BITSET` statement is used to decode flags from such a status value. Usually the fault status is read into an internal variable if the driver. Then the fault bits are decoded from this internal variable using the `BITSET` statement.



The bit position zero addresses the least significant bit in the source variable. The destination variable gets set to `1` or `true` if the addressed bit is set, to `0` or `false` if not. If the variable name is preceded by an exclamation mark, this mapping is inverted.

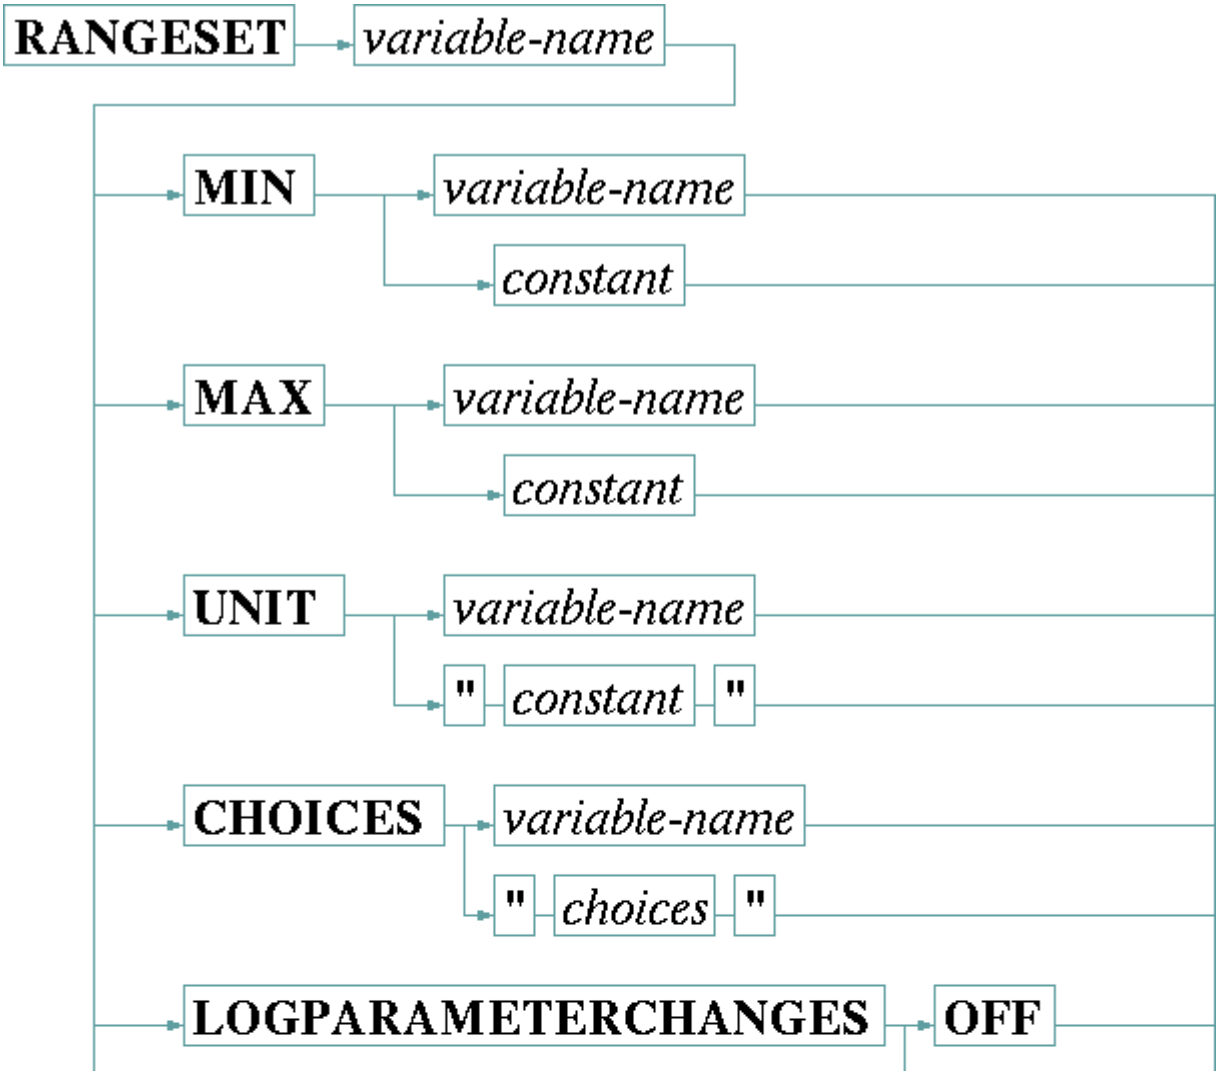
Example

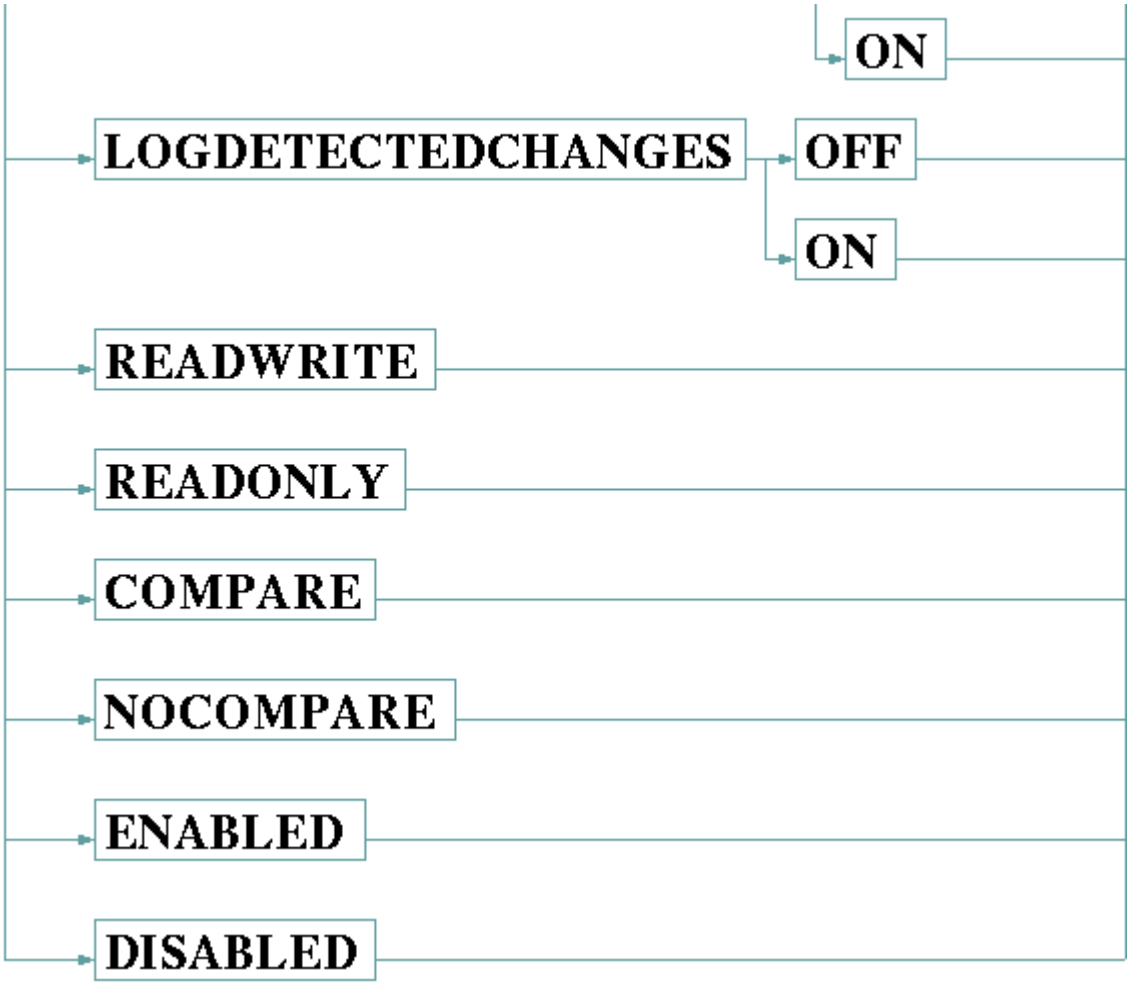
```
INPUT internal.flags
BITSET faults.01 = internal.flags  4    // Temperature
BITSET faults.02 = internal.flags  5    // Signal level
BITSET faults.03 = ! internal.flags  11 // Video lock (inv)
BITSET faults.04 = ! internal.flags  9  // Audio lock (inv)
BITSET faults.05 = internal.flags  13   // High BER
BITSET faults.06 = internal.flags  15   // Demodulator lock
BITSET faults.07 = internal.flags  14   // Conditional Access
```

The example above reads a value into the variable `internal.flags`. BITSET statements are used to extract seven faults flags from this variable. `internal.flags` must be declared `READONLY` to make this example work.

7.2.9.3 The RANGESET statement

The `RANGESET` statement changes several aspects of the range definition of a variable. It is intended to be used in drivers which read some capabilities (e.g. a frequency range) from the device itself.





The options which may follow the `RANGESET` statement are described in the table below:

MIN	Changes the minimum value for a numeric (`INTEGER` , `HEX` , `FLOAT`) variable. The new minimum value may be a constant numeric value or the contents of another variable. `MIN` applies to numeric variables only.
MAX	Changes the maximum value for a numeric (`INTEGER` , `HEX` , `FLOAT`) variable. The new maximum value may be a constant numeric value or the contents of another variable. `MAX` applies to numeric variables only.

UNIT	Changes the maximum value for a numeric (`INTEGER` , `HEX` , `FLOAT`) or a `ALARM` flag variable. The new unit string may e a constant value enclosed in double quotes or the contents of another variable. `RANGESET` / `UNIT` applied to `ALARM` flags changes the alarm description text. To make the unit string for a numeric variable look like the unit specified in the VAR statement, start the string with a space character (e.g. `dBm`). The `VAR` statement implicitly prepends this space character.
CHOICES	Changes the set of choices for a `CHOICE` variable. May be followed either by a variable name or by a quoted string defining the new list of choices. The list of choices is a comma separated list of strings, either defined as a constant enclosed in double quotes or read from the contents of the variable referenced after the `CHOICES` keyword. `CHOICES` applies to `CHOICE` variables only.
READWRITE	Makes the parameter writable from the user interface, overrides a former `READONLY` definition. `READWRITE` applies to all types of variables.
READONLY	Makes the parameter read only. `READONLY` applies to all types of variables.
LOGPARAMETERCHANGESON/OFF	Defines if this variables shall log changes which are commanded to it. Parameter changes are logged if this is set ON and the `logParameterChanges` switch in the device setup page is activated as well. `LOGPARAMETERCHANGES` is `ON` by default for all variables, hence you only need to state `LOGPARAMETERCHANGES OFF` for variables you want explicitly to be excluded from logging.

LOGDETECTEDCHANGESON/OFF	Defines if this variables shall log changes which are detected when reading back the values. Detected changes are logged if this is set `ON` and the `logDetectedChanges` switch in the device setup page is activated as well. `LOGDETECTEDCHANGES` is `ON` by default for all variables, hence you only need to state `LOGDETECTEDCHANGES OFF` for variables you want explicitly to be excluded from logging. Please note, the this modifier has no effect on read-only variables, they are not logged regardless of the logDetected setting.
COMPARE	Enables the read after write comparison check for this variable. This check generates a log message, if the value of the variable read back from the device differs from the commanded value. By default the read after write comparison check is enabled for all variables unless they are defined with the `NOCOMPARE` option in the VAR statement.
NOCOMPARE	Disables the read after write comparison check for this variable.
ENABLED	Enables a formerly disabled variable. `ENABLED` applies to all types of variables.
DISABLED	Disables a variable. Disabled variables show no value at the user interface, any user input is blocked. Disabled variables never cause a procedure which watches this variable to run. `DISABLED` applies to all types of variables.

Updating the range of a variable marks the variable to be read from the device as soon as possible.

The ***sat-nms*** user interface recognizes range definitions every time a window is opened. An already opened window does not change the range definitions of it's input elements. A driver should change variable ranges only due to information which is read once on power up or after a device has been switched on.

Example

```
PRINT "RMAF" INPUT "=" internal.rx.fmax
PRINT "RMF"  INPUT "=" internal.rx.fmin

RANGESET rx.frequency MAX internal.rx.fmax
RANGESET rx.frequency MIN internal.rx.fmin
```

The example above - taken from the SSE K-Star device driver - reads the valid frequency range for the device into the internal driver variables `internal.rx.fmax` and `internal.rx.fmin`. `RANGESET` statements then update the range definition for the `rx.frequency`. This is done in a procedure which is called once after the driver gains communication to the device.

7.2.9.4 The BITSPLIT statement

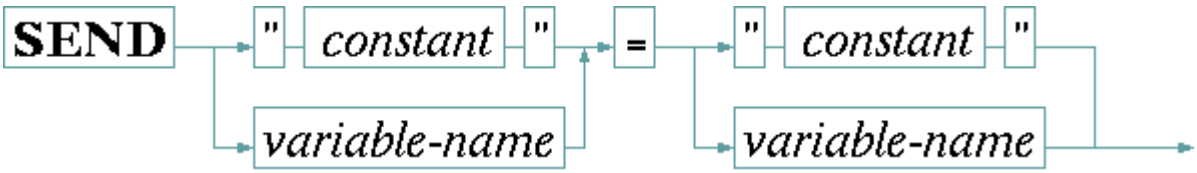
The `BITSPLIT` statement splits up a numeric variable in single bits. `BITSPLIT` will no longer be supported by future versions of the software and therefore should not be used in new device drivers.

7.2.9.5 The BITMERGE statement

The `BITMERGE` statement sets a numeric variable from a set of other variables each controlling one bit in the destination variable. `BITMERGE` will no longer be supported by future versions of the software and therefore should not be used in new device drivers.

7.2.9.6 The SEND statement

The `SEND` statement builds a parameter message from an address and value part and sends this to another device for execution, just like if the parameter had been issued by an operator of the software. The main purpose of this statement is to build logical devices interacting between other device by means of the universal driver language.



The syntax of the `SEND` statement looks much like the SET statement: Following the `SEND` keyword, you specify the destination and the value to be set, separated by `=` character. Both, the destination definition and the value to be sent, may either be quoted string or local variables of this driver:

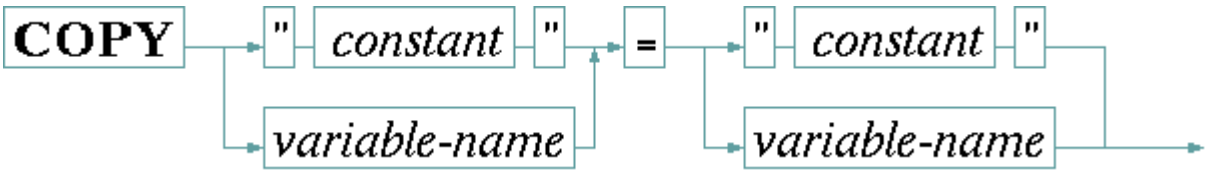
Quoted String	Variable

Quoted String	Variable
Destination	The message destination is literally specified like `DEVICE1.parameterName`. The contents of the variable (e.g. `config.destinationId`) is used as the destination ID for the parameter message. The variable must contain a string value representing a valid message ID
Value	The value to be set at the destination parameter is literally specified. Please note, that also numeric values must be enclosed in quotes here to be recognized al a literal constant.The contents of the variable is send as the value of the parameter message.

At execution time, the `SEND` statement checks if the destination parameter exists and converts the type of the value to be set as required. If this fails, you will find a `SEND to xxxx failed` informational message in the event log in this case.

7.2.9.7 The COPY statement

The `COPY` statement copies either a single parameter or the complete setting from one device to another



The syntax of the `COPY` statement looks much like the `SET` statement: Following the `COPY` keyword, you specify the destination and the source to be copied, separated by `=` character. Both, the destination definition and the value to be sent, may either be quoted string or local variables of this driver.

Quotes strings specify the device names or parameter IDs literally, when specifying variable names, the contents of the variable at execution time is used. Please note that it not possible to copy a complete device setup to a singel variable and vice versa. If the source is specified as a plain device name, the destination must be plain device name as well.

When copying single parameters, a new message is sent to the destination ID with the actual value of the source parameter. No type checking or conversion is done, the value is copied as it is.

When copying a complete device setup, all settings of the source device are collected to an unnamed / temporary device preset. This preset is applied to the destination device. Hence, all parameters the source device stores in presets are copied to the destination.

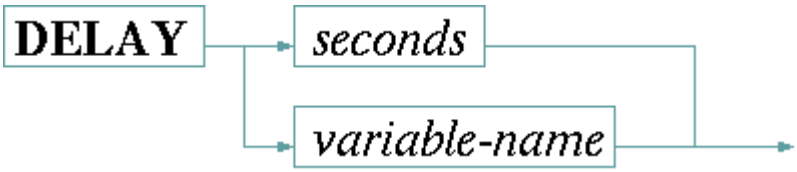
7.2.10 More statements

The ***sat-nms*** device driver definition language contains some more statements which have not yet been described in this document. They are:

DELAY	Pauses the device driver execution for some time.
LOG	Adds a message to the event log.
DRATE	Computes an interface data rate from a symbol rate.
SRATE	Computes a symbol rate from a interface data rate.
WRITEHEX	Outputs a variable containing a hex dump string as binary data.
READHEX	Reads binary data from the device and formats this as a hex dump string into a variable.
INVALIDATE	Invalidates a variable, marks it to be read back as soon as possible.
SYNC	Syncs a variable, updates the value to be commanded with the value recently read back from the device.
RAISECOMMFAULT	Makes the driver to raise a communication fault.

7.2.10.1 The DELAY statement

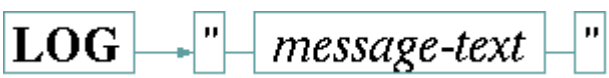
The `DELAY` statement pauses the driver execution for a given number of seconds. The delay may be specified as a (floating point) constant or a variable may be referenced which contains the time to delay.



You should use `DELAY` statements with care. Delaying the driver execution not only slows down the execution of the current procedure, it delays the polling cycle of all devices operated at this serial interface. With longer delay times, the MNC system may no longer be able to recognize device faults within a reasonable time.

7.2.10.2 The LOG statement

The `LOG` statement lets you add an arbitrary message to the MNC system's event log. This may be used to signal events which shall not be treated as a fault, but are to be recorded anyhow.



Messages generated by the `LOG` statement by default are of the priority `INFO`. If the first

character of the message to send is `2` or `3`, the first character is removed from the message and the priority id increased to `FAULT` (2), `ALARM` (3) or `WARNING` (4) respectively.

Example

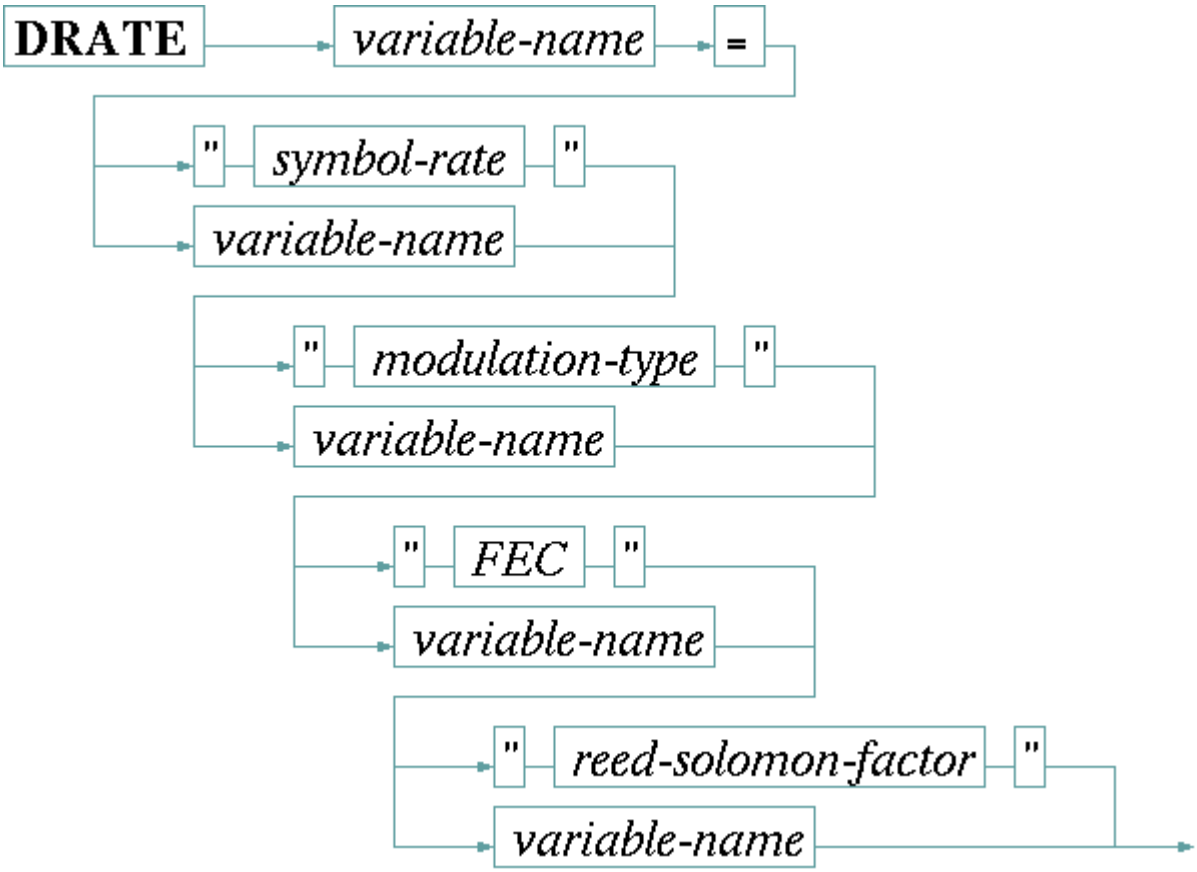
```
LOG "This is an informational message"
LOG "3This is an ALARM message !"
```

The example above adds two messages to the log. The message `This is an informational message` is added with priority `INFO`, the message `This is an ALARM message!` is added with `ALARM` priority.

Please note: although the priority `WARNING` is represented by the number 4, it's logical priority is between `INFORMATIONAL` and `FAULT`. This is because warnings have been added to the software lately and there had do be defined an unused number for the new priority.

7.2.10.3 The DRATE statement

The `DRATE` statement implements a data rate calculator which lets you convert a symbol rate to a interface data rate. This may be useful if a device driver shall supply both values, but the device itself only supports one of these settings.



The `DRATE` statement collects a symbol rate value, a modulation type, a FEC value and a

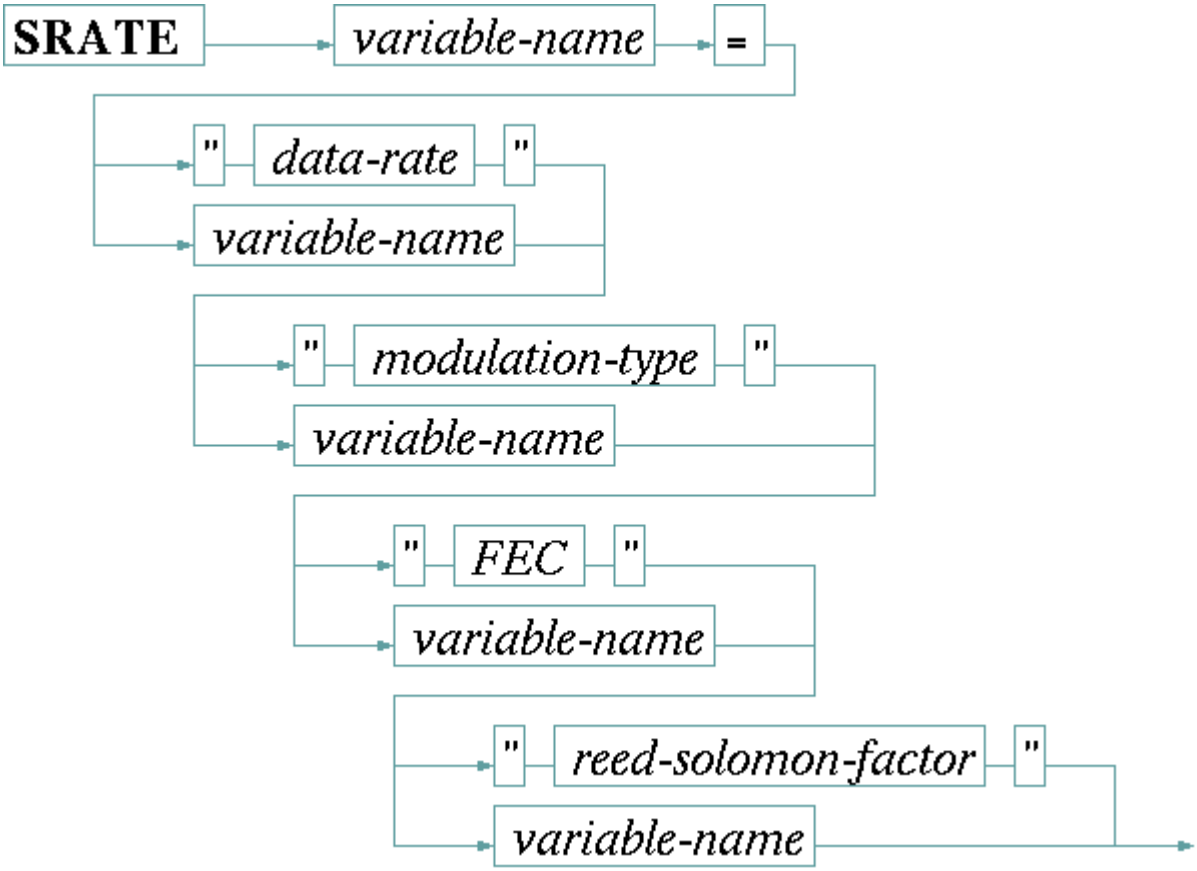
Reed-Solomon factor, computes an interface data rate from this and stores the result into the destination variable. The input data for the DRATE statement may be from constants given in double quotes or from the contents of driver variables.

The `DRATE` statement tries to guess the conversion factors from the input data following the rules described below:

- **modulation type**
  - Tries to guess the modulation type from the characters the token starts with. This catches all common names for modulation types.
  - `16*` : factor 4
  - `8*` : factor 3
  - `Q*` : factor 2
  - Everything else factor 1
- **FEC**
  - May be one of `1/2` , `2/3` , `3/4` , `4/5` , `5/6` , `6/7` , `7/8` or `8/9` .
  - Everything else is treated as `1/1` (no FEC).
- **Reed-Solomon factor**
  - Accepts any factor written as `nnn/mmm` , e.g. `188/204` .
  - If a single number is given, a denominator is assumed to be 204
  - Everything else is treated as `1/1` (no Reed-Solomon)

7.2.10.4 The SRATE statement

The `SRATE` statement implements a data rate calculator which lets you convert a interface data rate into a symbol rate. This may be useful if a device driver shall supply both values, but the device itself only supports one of these settings.



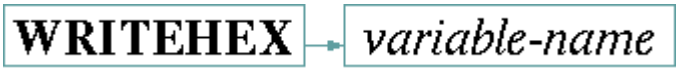
The `SRATE` statement collects a data rate value, a modulation type, a FEC value and a Reed-Solomon factor, computes the symbol rate from this and stores the result into the destination variable. The input data for the `SRATE` statement may be from constants given in double quotes or from the contents of driver variables.

The `SRATE` statement tries to guess the conversion factors from the input data following the rules described below:

- **modulation type**
  - Tries to guess the modulation type from the characters the token starts with. This catches all common names for modulation types.
  - `16* : factor 4
  - `8*` : factor 3
  - `Q*` : factor 2
  - Everything else : factor 1
- **FEC**
  - May be one of `1/2` , `2/3` , `3/4` , `4/5` , `5/6` , `6/7` , `7/8` or `8/9` .
  - Everything else is treated as `1/1` (no FEC).
- **Reed-Solomon factor**
  - Accepts any factor written as `nnn/mmm` , e.g. `188/204` .
  - If a single number is given, a denominator is assumed to be 204.
  - Everything else is treated as `1/1` (no Reed-Solomon)

7.2.10.5 The WRITEHEX statement

The WRITEHEX statement interprets the contents of a variable as a hex dump of a binary byte array and sends this binary data to the device after packing it into a protocol frame.



The WRITEHEX statement is used in the StandardBin.nc include file to define a convenient method of sending a command through the lowLevel driver variable for binary communication protocols. There is probably no other use for the WRITEHEX statement.

7.2.10.6 The READHEX statement

The READHEX statement reads a message from the device, strips off the protocol frame and formats the received binary data as a hex dump. This is assigned to a driver variable.

The READHEX statement is used in the StandardBin.nc include file to define a convenient method of reading back the device's reply through the lowLevel driver variable for binary communication protocols. There is probably no other use for the READHEX statement.

7.2.10.7 The INVALIDATE statement

The INVALIDATE statement marks a variable to be read from the device as soon as possible. It can be used if for instance a general mode setting has been changed at the device - requiring all parameter depending on this mode to be updated. INVALIDATE bypasses the *delayed read back* mechanism controlled by the config.readBackDelay setting, forces the read back in the same cycle if the GET procedure for the variable is located after the INVALIDATE statement within the driver.

For the INVALIDATE statement, use the keyword INVALIDATE followed by the name of the variable to be invalidated.

7.2.10.8 The SYNC statement

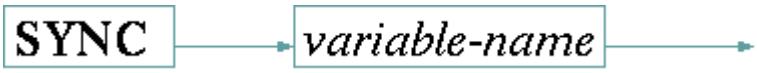
The SYNC statement *syncs* a variable, meaning that the variable's commanded value gets updated with the value recently read back from the device.

Normally, the device driver remembers a variable's value as it has been commanded from the GUI or from a logical device. When called in a PRINT or WRITE statement, this value will be used in favour of the value read back from the device. The driver uses this to check, if the commanded values has been accepted by the device.

When the device alters a commandable parameter autonomously, it may be desirable to accept

this value as the new value to be commanded. For example, imagine an antenna tracking controller device which accepts the pointing angles only as a triple az/el/pol. The operator commands all three angles to find the satellite and switches on tracking. The antenna controller tracks the satellite and as a consequence alters the pointing angles. If now one of the angles will be set in the GUI by the operator, the other two angles will revert to the values which had been set before tracking was switches on.

Using the SYNC statement after reading back the pointing values will help to avoid this situation.



For the `SYNC` statement, use the keyword `SYNC` followed by the name of the variable to be synced.

7.2.10.9 The RAISECOMMFAULT statement

The `RAISECOMMFAULT` statement causes a communication fault to be raised. This e.g. can be used, if the device returns some value which is not expected or that indicates that the device did not recognize the last command. The fault gets cleared once the driver successfully passed one more cycle.

For the `RAISECOMMFAULT` statement, use the keyword `RAISECOMMFAULT` followed by a quoted string containing a message to be shown with the fault.

7.3 The RPN language extension

The ***sat-nms*** device driver definition language has been designed to be easy to understand and to provide a set of commands which is optimized to program device drivers. It enables people with some technical understanding but without any programming experience to add new device drivers to the ***sat-nms*** system.

Some complex devices require the device driver to behave more intelligent than the device driver definition language can do. For such cases the RPN language extension has been added to the device driver language.

The RPN language extension adds some functionality of an RPN (RPN = Reverse Polish Notation) programmable pocket calculator to the device driver. With RPN commands a device driver procedure can do:

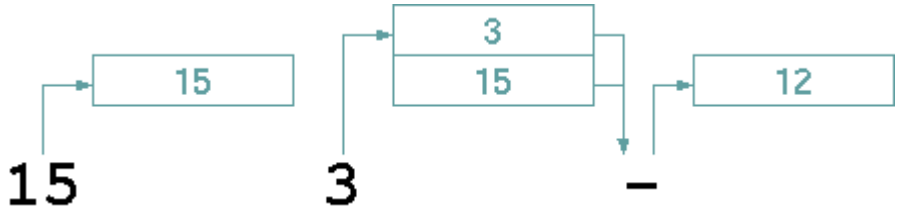
- Arithmetic operations.
- String manipulation operations.
- Text based I/O to the device.
- Loops, conditional branches.

Device drivers using RPN commands are not as easy to understand as standard device drivers are. Only experienced programmers should use these commands as bad designed RPN command sequences may compromise the stability of the whole MNC system.

7.3.1 The RPN stack

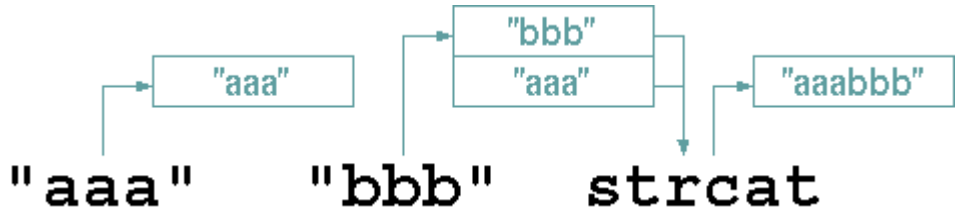
RPN (Reverse Polish Notation) is a way to define arithmetic operations which very efficiently can be used for computer programs. A number of pocket calculators use this method as well as programming languages like FORTH.

The example below illustrates how RPN works. Subtracting 3 from 15 you will be used to write as `15 - 3`. This is known as *infix* notation, the operator (`-`) is written in between the arguments it works on. With RPN (aka. *postfix* notation) the operator appears behind it's arguments:



- Writing `15` pushes this number on the stack.
- Now `3` pushes the second argument on the stack, the number `3` now appears on top of the `15`.
- Finally the `-` operator removes both numbers from the stack and replaces them by the result of the operation.

With the ***sat-nms*** device driver language, RPN operations are not limited to plain arithmetic. The example below illustrates a string concatenation:



The stack is able to store objects of different data types. Numbers, boolean values and character strings may be used. RPN functions automatically convert the type of their input data as required. The stack generally is not limited in size (the computer's memory size however limits the stack).

RPN operations may take an arbitrary number of parameters from the stack and they may leave an arbitrary number of results there. This makes functions possible which are much more complex than a simple `+` or `-`. Furthermore, the stack may be used as a storage for intermediate results. This together allows to perform quite complex operations very efficiently.

There is one stack for each device which keeps it's contents between driver procedures and

cycles. While this feature enables you to do very sophisticated things with the stack, you should be careful not to leave accidentally something on the stack at the end of an operation. The stack may grow with each cycle of the device driver, eating up slowly the whole available memory. Then, after hours, the MNC application aborts due to a lack of memory. There is a `clr` RPN command which clears the stack, you should call it at the end of an RPN sequence.

7.3.2 The { ...} statement

A sequence of words enclosed in curly braces is recognized by the device driver as an RPN command sequence. Within the RPN sequence commands must be separated by whitespace. Each word is interpreted as one of the following:

Variable names	cause the interpreter to push the variable's contents onto the stack.
Table names	cause the interpreter to remember this translation table and use it for the next `rxlt` / `xlt` command(s).
Numeric (decimal) constants	are pushed onto the stack as double precision floating point values.
Character strings (in double quotes)	are pushed as they are.
Commands / keywords	are executed as the RPN command reference in the following chapter describes.

Example

```
{
   "ENQ;AUN" prt                    // request the number of
   inp "=" find                     // audio streams, get the reply
   !internal.numAudio               // and store it

   internal.numAudio if
    ""                              // audio stream list
    0                               // loop counter
    do
     "ENQ;AUX=" over "d04" fmt strcat prt  // request one entry
     swap                           // get the list on top
     inp "=" find                   // the complete entry
     dup "," trm 2 substr           // entry number 2 digits
     " " strcat                     // delimiter
     swap "," find "," find         // language description
     strcat strcat "\n" strcat      // append the reply
     swap                           // loop counter on top
     1 +                            // increment it
     internal.numAudio 1 -          // decrement numAudio,
     !internal.numAudio             // loop until there are more
    internal.numAudio while         // audio streams
    drop                            // the loop counter
   else
    "NONE\n"
   endif
   !audioList
   clr                              // due to paranoia ;-)
}
```

The example above - taken from the Tandberg-Alteia device driver - fills the variable `audioList` with a newline separated list of available audio streams as reported by the IRD. The RPN sequence first gets the number of available streams from the IRD and stores this into `internal.numAudio`, Then, unless `internal.numAudio` is zero, the program builds the list from the information returned by the IRD for each stream.

7.3.3 RPN command reference

The table below summarizes all commands and operations which are accepted by the device driver in RPN mode. The second column of the table describes how a command changes the stack. Left of the `--` the objects the operation takes from the stack are listed. The TOS (top of stack) is the rightmost value. Right of the '--' the results the operation leaves on the stack are shown.

command	stack usage	description

command	stack usage	description
variable-name	**-- v**	Pushes the contents of the variable onto the stack. The type of the variable is retained (`CHOICE` parameters are represented by string values).
numeric-constant	**-- v**	A numeric value (only decimal notation is allowed) is pushed as a floating point number onto the stack.
%numeric-constant	**-- v**	A numeric value (decimal) preceded by a `%` character is pushed as a long integer number onto the stack.
#hex-constant	**-- v**	A hexadecimal numeric value preceded by a `#` character is pushed as a long integer number onto the stack.
"text"	**-- v**	A text in double quotes is pushed onto the stack as a string constant.
! *variable-name*	**v --**	The exclamation mark, followed by a variable name, tells the driver to take one value from the stack an store it into the variable. Type conversion and range check is done as defined at the VAR statement which created the variable.
^ *variable-name*	**v --**	The caret, followed by a variable name works much like store operator described above. However, while the store (`!`) operator refers to the value the device driver read from the device, the caret operator loops the value to the driver as if an operator had commanded it.
<	**x y -- b**	Compares `x` and `y` numerically. The result is `true` if $x < y$.
=	**x y -- b**	Compares the string representation of x and y. The result is `true` if $x = y$. Be careful when comparing floating point values.
>	**x y -- b**	Compares `x` and `y` numerically. The result is `true` if $x > y$.
-	**x y -- z**	Subtracts two values. The result is $x - y$.
/	**x y -- z**	Divides two values. The result is x / y. With $y = 0$ the result always is zero (although this is mathematically not correct).
*	**x y -- z**	Multiplies two values.
+	**x y -- z**	Adds two values.
@	**'s' -- z**	Replaces the name of a parameter by it's value. The parameter name must be a complete parameter ID, the value is that one displayed at the GUI, not the recently commanded one. If `@` fails, the string `0` ist left on the stack.

command	stack usage	description
binand	**x y -- z**	Performs a bitwise AND of two numeric operands.
binneg	**x -- z**	Binary negates the value on the stack.
binor	**x y -- z**	Performs a bitwise OR of two numeric operands.
binxor	**x y -- z**	Performs a bitwise XOR of two numeric operands.
bit	**n p -- b**	Isolates a bit value from a numeric value. Leaves a boolean flag on the stack which is true if the bit number `p` of the value `n` was set. Bit number 0 denotes the least significant bit in `n` .
clr	**... v --**	Clears the stack.
copy	**'s' 'd' --**	Copies a single parameter or a complete device setup from one device to another. `s` , `d` are interpreted as source and destination of the operation, must both be either plain device names or fully qualified parameter IDs (e.g. `MYDEVICE.grp.parName`). When copying complete device setups, this is done via the device preset facility: a temporary / unnamed device preset is taken from the source device an applied to the destination device.
cut	**'s' n -- 's'**	Cuts the string `s` to the length of `n` characters. If `n` is greater than the length of the string to cut, the latter is leaved unchanged.
debug	**x --**	Takes a numeric value from the stack. Turns on debugging output if non-zero. The debugging output can be watched on the debug console window of the MNC software.
do	**--**	Starts a **do ... while** or a **do ... until** loop.
drop	**v --**	Removes one value from the stack.
dup	**v -- v v**	Duplicates the value on top of the stack.
else	**--**	Part of the **if ... else ... endif** construct.
endif	**--**	Closes an **if ... endif** or an **if ... else ... endif** construct.
find	**'s' 'p' -- 's'**	Finds the pattern `p` in the string `s` . Removes the beginning if `s` including the first occurrence of the pattern `p` . The result starts with the character following the first occurrence of `p` in `s` . If `p` is not found in `s` , find leaves an empty string on the stack.

command	stack usage	description
fmt	**n 'fmt' -- 's'**	Formats a numeric value according to format specification given in `fmt`. Leaves the formatted number as a string on the stack. The format specification follows the same rules the FMT option of the PRINT statement does.
func	**v 'fname' -- v**	Processes a numeric value through a tabular function using linear interpolation. First takes the name of the function to apply from the stack, then the value to process. The interpolated value id pushed back to the stack. Works much like the FUNCTION clause available in most I/O statements of the driver language. Chapter Function tables in I/O functions gives an extensive description about functions an how they are used.
hex	**'x' -- n**	Interprets the top of the stack as the string representation of a hexadecimal number. Leaves the numeric value on the stack.
if	**n --**	Start a **if ... endif** or a **if ... else ... endif** clause. Takes one value from the stack. If this value is non-zero, the commands between **if** and **else** are executed.
inp	**-- 's'**	Reads one message from the device and places the data as a string on the stack. The protocol frame is removed.
log10	**x -- z**	This is the inverse function to **pow10**. It takes the common logarithm of the value on the TOS. To use this function to convert a `mW` expressed power to `dBm` follow this example: `mwval log10 10 *` converts the contents of `mwval` from `mW` to `dBm`.
not	**v -- v**	Negates the top of stack. Works with boolean values, numeric values (non-zero is turned into 0, 0 is turned into 1), and common string codings of boolean states.
over	**a b -- a b a**	Copies the value located one below the TOS on top of the stack.
pow	**x y -- z**	Raises `x` to the power of `y`. May be used to compute the square of a number (`3 2 pow` leaves `9` on the stack). Floating point numbers are allowed for both operands, hence you may compute a square root like this: `myvar 0.5 pow` leaves the square root of the contents of myvar on the stack.
pow10	**x -- z**	Raises 10 to the power of `x`. This mainly is intended to convert RF power values expressed in `dBm` to `mW`. Example: `dbmval 10 / pow10` converts the contents of `dbmval` from `dBm` to `mW`, leaves the latter value on the stack.

command	stack usage	description
prt	**'s' --**	Takes a value from the stack and sends its string representation to the device after adding the protocol frame.
rot	**a b c -- b a c**	Rotates three values on top of the stack.
table **rxlt**	**'s' -- 's'**	Translates a string value through the given translation table. Translates from right to left. Uses the table with the name defined somewhere before the **rxlt** command. The table is *not* pushed to the stack, so the exact position of the table name does not matter.
send	**'v' 'd' --**	Sends a message to another device, setting a parameter at this device. `d` is interpreted as the full parameter ID of the message destination (e.g. `MYDEVICE.grp.parName`), `v` is the value to be set there.
shl	**'x' 'y' -- 'z'**	Shifts `x` left by `y` positions. treats all values as long integers.
shr	**'x' 'y' -- 'z'**	Shifts `x` right by `y` positions. treats all values as long integers.
strcat	**'s' 's' -- 's'**	Concats two string values.
substr	**'s' n -- 's'**	Removes `n` character from the beginning of a string value.
swap	**a b -- b a**	Swaps two values on top of the stack.
trm	**'s' 'p' -- 's'**	Cuts the string `s` at that point where the pattern `p` is found in the string. Leaves the string `s` unchanged if `p` does not exist in `s`
until	**n --**	Closes a **do ... until** loop. Takes one value from the stack, loops again if this is zero.
while	**--**	Closes a **do ... while** loop. Takes one value from the stack, loops again if this is non-zero.
table **xlt**	**'s' -- 's'**	Translates a string value through the given translation table. Translates from left to right. Uses the table with the name defined somewhere before the **xlt** command. The table is *not* pushed to the stack, so the exact position of the table name does not matter.

command	stack usage	description

7.4 SNMP device classification and variable binding

As of version 3.1.610 the ***sat-nms*** MNC provides an universal SNMP agent which publishes a limited number of device parameters in a fixed, table oriented MIB. This SNMP agent permits to monitor and partially control any ***sat-nms*** MNC using the same MIB - regardless of the device configuration of the particular MNC.

The MIB provides one table which contains all devices which are configured in the ***sat-nms*** MNC. No special mapping is necessary for this table as there are only very common parameters like the device name, its fault state or its administrative state in this table.

Beside this, the MIB contains a couple of tables, each representing all devices belonging to a so called *device class*. For instance, there is one table containing all HPAs in the MNC and one table containing all waveguide switches. These class specific tables contain some parameters which are common to the devices of the particular class. The HPA table contains parameters for tx-on, for attenuation and forthe measured output power for each device, the waveguide switch table provides a parameter for the switch position.

As device drivers sometimes use different parameter names for the same or similar function, an individual mapping from the *universal* parameter in the MIB to the real parameter in the device is necessary for every single ***sat-nms*** device driver. Device drivers which do not contain any information about the device class this device belongs to and how the parameters are to be mapped into the MIB only appear in the in the general device table of the MIB.

A ***sat-nms*** device (physical or logical) may be represented by multiple device classes in the MIB or by multiple instances of the same class. For example a combined upconverter and HPA may appera as a HPA in this table (with its HPA specific parameters) and a second time in the upconverter table with its frequency parameter.

Also devices consisting of multiple modules can be treated this way in the MIB, there are quad block upconverter on the market which provide four independent converter modules in one device. Such a device can be mapped in way, that it appears as four BUC devices in that table.

7.4.1 Device driver syntax for SNMP definitions

SNMP definitions are coded in the device driver file as special comment lines. This ensures, that new device drivers which include SNMP definitions can be run on older ***sat-nms*** systems which where delivered before this SNMP feature was introduced.

SNMP definitions involve two keywords, `@class` and `@varbind` . `@class` makes the device member of a certain device class and creates a row for tis device in the table of the referenced device class. `@varbind` maps a SNMP OID to a certain ***sat-nms*** driver variable. All `@varbind` definitions following a `@class` definition refer to this and may only map OID names which are valid for the device class defines above.

The example below explains how to define the SNMP mapping for a device:

```
// @class   HPA
// @varbind mncHpaTxOn        tx.on
// @varbind mncHpaAttenuation  tx.attn
// @varbind mncHpaOutputPower  tx.measuredLevel
// @varbind mncHpaHelixCurrent meas.iHelix
// @varbind mncHpaState       state
```

The `@class` definition identifies the device as a power amplifier and creates an instance for the device in the HPAs table. `@class` and the class name must appear in the same line and there must not be any trailing text right of the class name in the line. A list of valid class names may be found in chapter List of SNMP device classes and OID namesThe `@varbind` definitions below map the OIDs defined for one row of the HPA table to the corresponding variables in the driver. Each `@varbind` keyword must be followed by a valid OID name for this device class and then by the name of a device driver variable. Again, all three words must appear in the same line to be recognized correctly.

As mentioned above, a device may be part of multiple device classes at a time, it also may create multiple rows in the same SNMP table to map identical modules in the device to 'copies' of the device in the table. The example below illustrates this for a dual block upconverter:

```
// @class   BUC 1
// @varbind mncBucTxOn       tx.on.1
// @varbind mncBucInputAtten  tx.attn.1
// @class   BUC 2
// @varbind mncBucTxOn       tx.on.2
// @varbind mncBucInputAtten  tx.attn.2
```

Two `@class` definitions create two rows in the BUC table of the MIB. The number 1, 2 following the class name set the module index in the table, this can be used to differentiate between the two BUCs.

Device drivers maintained by SatService always list all `@varbind` OIDs defined for the `@class` of the device. Parameters which have no mapping for the particular device driver are listed with `!varbind` instead of `@varbind` . This prevents the parser from binding this OID to a variable of the driver, at the same time the complete list of `@varbind` OIDs stays visible in the device driver text for reference.

With the mncTarSelTargets `@varbind` (links the target names defined by a SatService ACU-ODM into the MIB), the software uses a `*` wildcard to denote the position of the target index in

the ***sat-nms*** variable name:

```
// @class   TARSEL
// @varbind mncTarSelMoveToTarget      target.goto
// @varbind mncTarSelTargets           target.*
```

7.4.2 List of SNMP device classes and OID names

The following list shows the SNMP device classes known by the software and the valid OID names for each device class. Most OID names are self-explanatory. The MIB file `satnms-mnc-mib.txt` gives more detailled information about each value.

```
ACU                          -- Antenna controller
   mncAcuAzimuthState           r/o
   mncAcuElevationState         r/o
   mncAcuPolarizationState      r/o
   mncAcuAzimuthTarget          r/w
   mncAcuElevationTarget        r/w
   mncAcuPolarizationTarget     r/w
   mncAcuBeaconFrequency        r/w
   mncAcuBeaconLevel            r/o
   mncAcuMonopulseAzError       r/o
   mncAcuMonopulseElError       r/o
   mncAcuTrackingState          r/o
   mncAcuTargetName             r/o

TRX                          -- Tracking receiver
   mncTrxFrequency              r/w
   mncTrxBeaconLevel            r/o
   mncTrxSignalOkState          r/o
   mncTrxBeaconRelativeLevel    r/o

HPA                          -- Power amplifier
   mncHpaTxOn                   r/w
   mncHpaAttenuation            r/w
   mncHpaOutputPower            r/o
   mncHpaHelixCurrent           r/o
   mncHpaState                  r/o
   mncHpaBeam                   r/w
   mncHpaOutputPowerWatt        r/o
   mncHpaPrimaryTemp            r/o
   mncHpaSecondaryTemp          r/o
   mncHpaCurrent                r/o
   mncHpaOperatingHours         r/o

EIRP                         -- EIRP control device
   mncEirpTxOn                  r/w
```

```
    mncEirpCommandedPower        r/w
    mncEirpMeasuredPower         r/o

BUC                             -- Block upconverter
    mncBucTxOn                   r/w
    mncBucFrequency              r/w
    mncBucAttenuation            r/w

UCONV                           -- Upconverter
    mncUconvTxOn                 r/w
    mncUconvFrequency            r/w
    mncUconvAttenuation          r/w

DCONV                           -- Downconverter
    mncDconvRxOn                 r/w
    mncDconvFrequency            r/w
    mncDconvAttenuation          r/w

TLT                             -- Test loop translator
    mncTltTxFrequency            r/w
    mncTltRxFrequency            r/w
    mncTltAttenuation            r/w
    mncTltLoFrequency            r/w

UPC                             -- Uplink power control
    mncUpcEnable                 r/w
    mncUpcInputDelta             r/o
    mncUpcOutputDelta            r/o

DEICE                           -- De-icing controller
    mncDeiceEnable               r/w
    mncDeiceIceCondition         r/o
    mncDeiceRainCondition        r/o
    mncDeiceState                r/o

DEHYD                           -- Waveguide pressurizer
    mncDehydEnable               r/w
    mncDehydPressure             r/o

   mncModPilots                  r/w
```

7.5 Device driver examples

The following pages contain two examples for a device driver, taken from the***sat-nms*** device driver library. While the first driver is a quite simple implementation, the second driver makes use of the RPN language extension and other features.

- NDSatCom-KuBand-Upconverter
- Tandberg-Alteia

7.5.1 NDSatCom-KuBand-Upconverter Example

```
//
//  Device driver for the ND SatCom Ku-band upconverter.
//
//
//  CHANGE RECORD:
//
//  2001-05-05   1.00  initial version.
//  2001-06-23   1.01  the get procedure also depends on the tx.gain and
//                     the tx.frequency parameter.
//  2001-06-27   1.02  info.type set to NDSatCom-Upconverter
//  2001-08-09   1.03  changed info.type to match the file name.
//

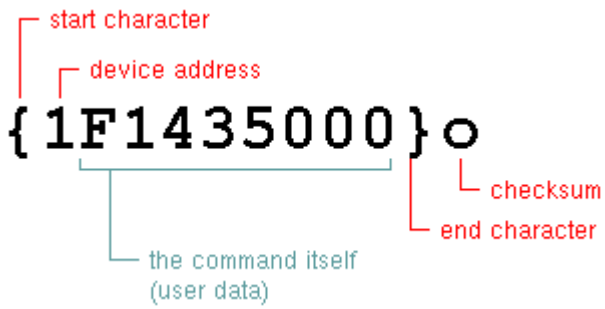
7.6 Device communication protocols

A device communication protocol encapsulates the recurrent operations to handle things like

start and stop characters or checksums with each message to be sent or received. The example below shows the complete message a ND-SatCom upconverter receives to tune its frequency. The pure command is `F1435000` (sets the frequency to 14,350.00 MHz). The protocol frame starts with a `{` followed by the device address. The command is terminated by `}` and finally a checksum character is sent.



A device communication protocol in the ***sat-nms*** software adds the protocol frame data (here marked red) to each message sent by a device driver with a `PRINT` or `WRITE` statement. The `PRINT` or `WRITE` statement creates the user data, the pure command. The protocol handler looks up the device address in the setup settings for the device, adds the start and stop characters and calculates the checksum over the message. The other way round, for each message received, the protocol handler strips off the protocol frame data and verifies the address and checksum fields. An `INPUT` or `READ` statement then receives the pure command data.

With the ***sat-nms*** software, new protocol definitions may be added to the software, simply by editing a text file for the new type of protocol frame which is needed.

7.6.1 Writing a communication protocol definition

As mentioned above, protocol definitions are coded as simple text files. When the MNC program starts, it *compiles* the protocols needed for it's equipment setup to memory. Writing a protocol definition means editing such a text file and storing it at a place in the MNC computer where the MNC program searches for these files.

In a communication protocol definition file, you compose the protocol frame around a command from elements like characters, checksums or strings using a couple of keywords. The protocol definition language is quite simple, but powerful enough to specify almost all communication protocols used by satcom equipment.

A MNC system keeps all protocol definitions in a subdirectory called `protocols`. On standard installations this is the directory `/home/satnms/protocols`. The names of the protocol files consist of the protocol name followed by the extension `.proto`.

If you are writing the device driver on a Linux based MNC or NMS computer, you may want to use the VI text editor or mcedit (included in midnight commander) text editor for this. Both has been configured to colorize device driver files on these machines. We also providing syntax definitions for Visual Studio Code. Please ask your contact at SatService for details.

You also may copy protocol definition files to a MS-Windows based computer to edit them there. If you do this, you should consider the following:

- Protocol files are Unix based text files. Lines are terminated with a line-feed character only. Your favorite MS-Windows text editor may have problems to show these files.
- Unix / Linux is case sensitive with file names. Be sure that you don't mess up the case of characters in file name when you copy files between Unix and MS-Windows.

7.6.2 General file format

The protocol definition language uses a file format which is very similar to that one used with ***sat-nms*** device drivers. Like with device drivers the following applies:

- Whitespace (space characters, tabs, line breaks) separates words.
- Line breaks have no special termination function.
- All keywords are in upper case letters.
- Comments in C/C++ style are recognized (both, `/* ... */` and `// ...` comments).

Beside this, each protocol definition file has the same simple structure:

- The file starts with an (optional) comment block and some common definitions.
- Then, following the TRANSMIT keyword, the specification how a message shall be composed during transmit is given.
- Then the RECEIVE keyword starts the specification how to parse incoming data.

Below, an example for a protocol definition file is shown.

```
//
//  The communication protocol used with SSE devices in NPI mode.
//

COMMENT  "SSE-NPI 1.00 020108"
CLASS    TTYProtocol

/** packet send procedure ***********************************************/

TRANSMIT

  CHAR       2              // start byte, STX
  CHAR       "F"            // source (master) LU
  CHAR       "F"
  ADDRESS    TEXT           // destination (slave) LU, 2 characters
  HEXLENGTH  0              // 2 characters hex coded data length
  USERDATA                  // the command string
  CHECKSUM   SUM8H 1 -1      // checksum 2 characters
  CHAR       3              // end byte, ETX

/** packet receive procedure ********************************************/

RECEIVE

  START      2              // start byte, STX
  ADDRESS    TEXT           // source (slave) LU
  CHAR       "F"            // destination (master) LU
  CHAR       "F"
  HEXLENGTH  0              // 2 characters hex coded data length
  USERDATA                  // the response string
  CHECKSUM   SUM8H 1 -1 2    // checksum 2 characters
  CHAR       3              // end byte, ETX
```

7.6.3 Global definitions

The first section of the protocol definition file defines the protocol identification string and the Java class which is responsible to perform the I/O operations at runtime.

The `COMMENT` statement defines an identification string which is passed to the user interface. An operator can identify the type and version of a communication protocol used with a certain device.

The text following the `COMMENT` keyword is free field and principally may contain any

information. The device protocols coming with the ***sat-nms*** software all follow a convention which defines the comment string as

"protocol-name X.YY YYMMDD"

where `X` is the major version number of the protocol, `YY` the minor version number and `YYMMDD` the release date of this protocol version. It is recommended that customer defined device protocols follow this scheme, too.

The `CLASS` statement defines the Java class used perform the protocol I/O steps during runtime of the MNC software. Actually `TTYProtocol` is the only protocol class which is applicable for customer defined protocol definitions.

Some communication protocols may be configured in some aspects of their functionality by applying protocol parameters to them. This is done with the `PROTOCOLPARAMETER` statement:

There may multiple `PROTOCOLPARAMETER` statements in one protocol definition file, each defining one aspect of the communication protocol. The `key` defines the parameter to set, `value` is the value to be assigned to this parameter.

Protocol parameters may be set either in the protocol definition file (thus defining the parameter for all uses of the protocol) or in the device driver. A definition in the device driver overwrites the setting in the protocol file.

ATTENTION: If you have multiple devices in the same device thread (`INTERFACE`) using different device drivers, the result is unpredictable if the drivers do not make exactly the same protocol parameter settings.

Example

```
PROTOCOLPARAMETER "post.content.type=application/xml"
```

7.6.4 TX message elements

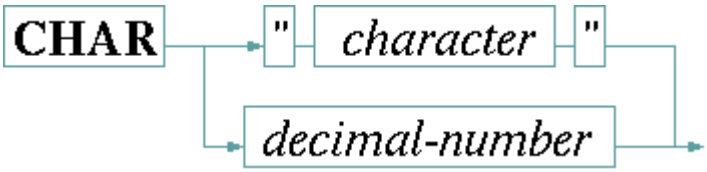
Starting with the `TRANSMIT` keyword, the second section of the protocol definition specifies the steps required to compose a valid protocol frame which is sent to the device.

The protocol frame definition consists of a sequence step specifiers, represented by a keyword followed by a defined number of parameters each. The step specifiers recognized in the the `TRANSMIT` section are:

CHAR	Outputs a single character.
ADDRESS	Outputs the device address.
USERDATA	Outputs the user data.
CHECKSUM	Outputs a message checksum.
DATALENGTH	Outputs a data length field (binary).
HEXLENGTH	Outputs a data length field (hex).
SEQUENCE	Outputs a binary message sequence number.

7.6.4.1 CHAR

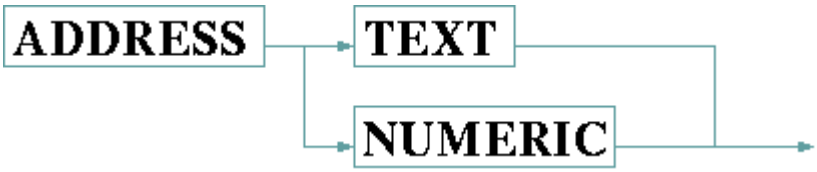
The CHAR step outputs a single character (byte).



The value may be specified as a single character in double quotes or as a decimal number in the range `0 ... 255`.

7.6.4.2 ADDRESS

The `ADDRESS` step outputs the device address.



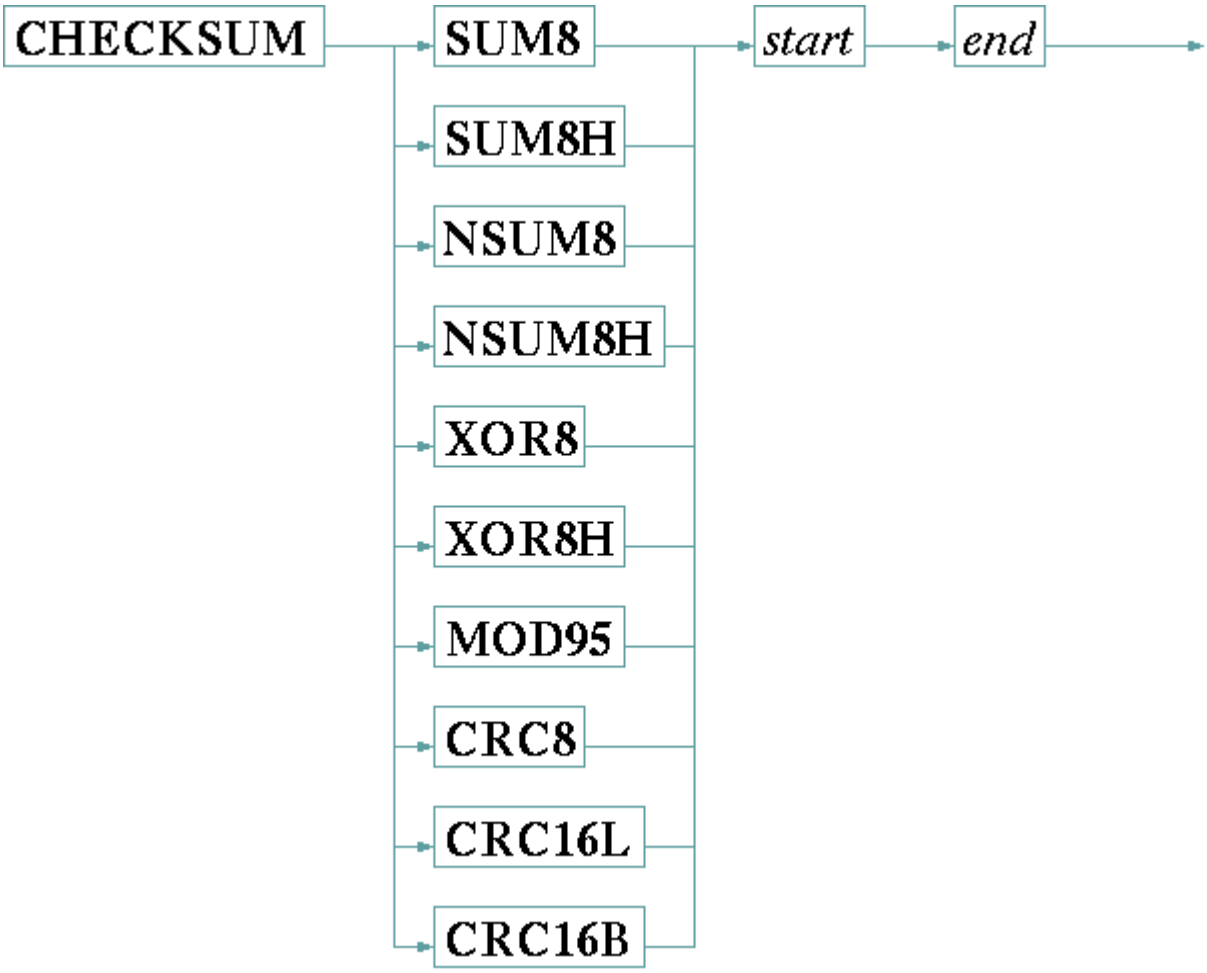
The `ADDRESS` keyword must be followed by one of `TEXT` or `NUMERIC`. If `TEXT` is specified, the address is output as a character string as it is entered at the user interface to the `address` configuration variable. If `NUMERIC` is specified, the address string is converted to a integer number and output as a single byte of this value.

7.6.4.3 USERDATA

The `USERDATA` step copies the user data as it was generated from the `PRINT` or `WRITE` statement in the device driver to the output.

7.6.4.4 CHECKSUM

The `CHECKSUM` step outputs a checksum calculated from the message contents.



The parameters of this step specifier are:

SUM8	Creates a one byte checksum by adding all bytes and truncating the sum to the lowest 8 bits.
SUM8H	Like `SUM8`, but the checksum is coded as a 2 digit hex number.
NSUM8	Creates a one byte checksum by adding all bytes, taking the negative value of the sum and then truncating the sum to the lowest 8 bits.
NSUM8H	Like `NSUM8`, but the checksum is coded as a 2 digit hex number.
XOR8	Creates a one byte checksum by XOR-ing all specified bytes.
XOR8H	Like `XOR8`, but the checksum is coded as a 2 digit hex number.
MOD95	Creates the one character *modulo 95* checksum, known from the protocol used by Miteq devices (see below).

CRC8	Creates a one byte `CRC8` checksum.
CRC16L	Creates a two byte `CRC16` checksum, using the ARC/LHA CRC algorithm. Places the least significant byte first (little endian).
CRC16B	Creates a two byte `CRC16` checksum, using the ARC/LHA CRC algorithm. Places the most significant byte first (big endian).
start	The buffer position of the first character to be included in the checksum computation (0 means the first character).
end	The buffer position of the last character to be included in the checksum computation, relative to the actual position (-1 means the character left of the first checksum character).

The `MOD95` type checksum is computed following the formula:

$$Checksum = 32 + MOD_{95}\left[\left(\sum_{i=1}^{N} message\ byte_i\right) - (32 * N)\right]$$

7.6.4.5 DATALENGTH

The `DATALENGTH` protocol step outputs a packet length field.

The packet length is computed as the length of the user data string created by the `PRINT` or `WRITE` statement in the device driver plus the offset defined as a decimal number. It is coded as a one byte binary.

7.6.4.6 HEXLENGTH

The `LENGTH` protocol step outputs a packet length field.

The length is computed as the length of the user data string created by the `PRINT` or `WRITE` statement in the device driver plus the offset defined as a decimal number. It is coded as a two character hex string.

7.6.4.7 SEQUENCE

The `SEQUENCE` step outputs a one byte binary sequence number.

The sequence number gets incremented with each message that has been sent.

7.6.5 RX message elements

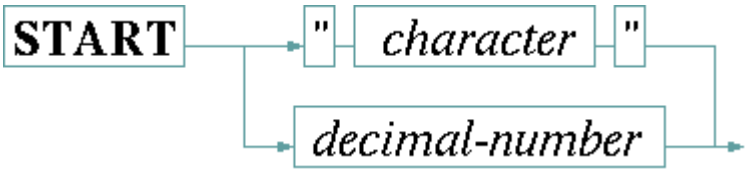
Starting with the `RECEIVE` keyword, the third section of the protocol definition specifies the steps required to parse a protocol frame which is received from the device.

The protocol frame definition consists of a sequence step specifiers, represented by a keyword followed by a defined number of parameters each. The step specifiers recognized in the the RECEIVE section are:

START	Reads a message start character.
CHAR	Reads a single character.
ADDRESS	Reads the device address.
USERDATA	Reads the user data.
STRING	Reads a terminated string as the user data
CHECKSUM	Reads a message checksum.
DATALENGTH	Reads a data length field (binary).
HEXLENGTH	Reads a data length field (hex).

7.6.5.1 START

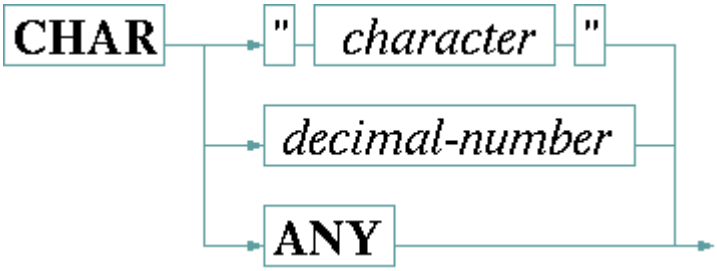
The `START` protocol step reads (and discards) all incoming data until the specified start character is received. The start character is not assumed to be part of the user data.



The character value may be specified as a single character in double quotes or as a decimal number in the range `0 ... 255`.

7.6.5.2 CHAR

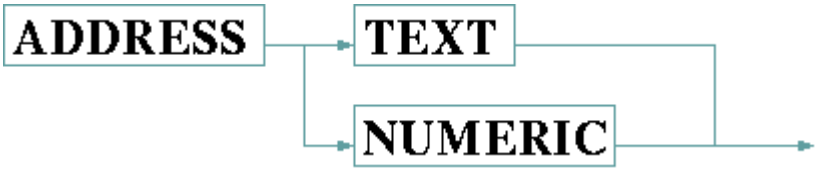
The `CHAR` step reads a single character and compares this to the expected value. If another character than expected has been received, the reception of this message is aborted and a communication fault is reported. The character received is not treated as part of the user data.



The value may be specified as a single character in double quotes or as a decimal number in the range `0 ... 255`. The special value `ANY` may be specified to make the `CHAR` step accept any character.

7.6.5.3 ADDRESS

The `ADDRESS` step reads the device address and compares it to the address value set in the device's setup menu. If the `ADDRESS` step received other data than expected, the reception of this message is aborted and a communication fault is reported.



The `ADDRESS` keyword must be followed by one of `TEXT` or `NUMERIC`:

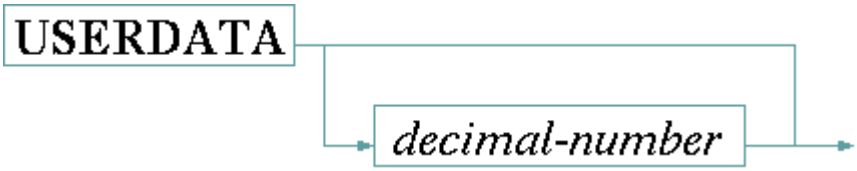
If `TEXT` is specified, the step reads as many characters as the address string configured for this device is long. The address is compared character by character to the received data.

If `NUMERIC` is specified, one character (byte) is read. The address string is converted to a integer number and compared to the received byte.

7.6.5.4 USERDATA

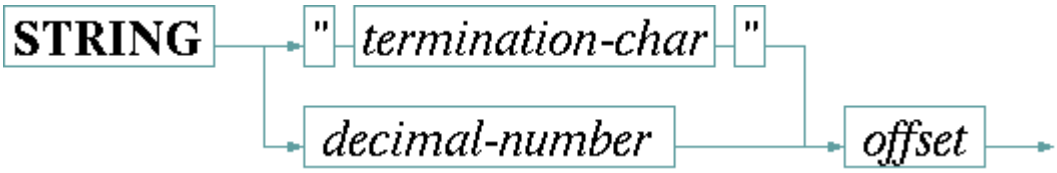
The `USERDATA` step reads a known number of bytes and returns these as the user data of the message. USERDATA requires to know the number of bytes to read, from one of these sources:

- A DATALENGTH protocol step appearing above the `USERDATA` step in the protocol definition.
- A HEXLENGTH protocol step appearing above the `USERDATA` step in the protocol definition.
- A fixed number of bytes, specified by a number following the `USERDATA` keyword. If the protocol definition contains a `DATALENGTH/HEXLENGTH` step and an explicitly given length in the `USERDATA` step as well, the length specified with the `USERDATA` step has precedence.



7.6.5.5 STRING

The `STRING` step reads a character string of variable length which is terminated by a known character. The received data may be truncated by a certain number of character before it is returned as the user data part of the message.



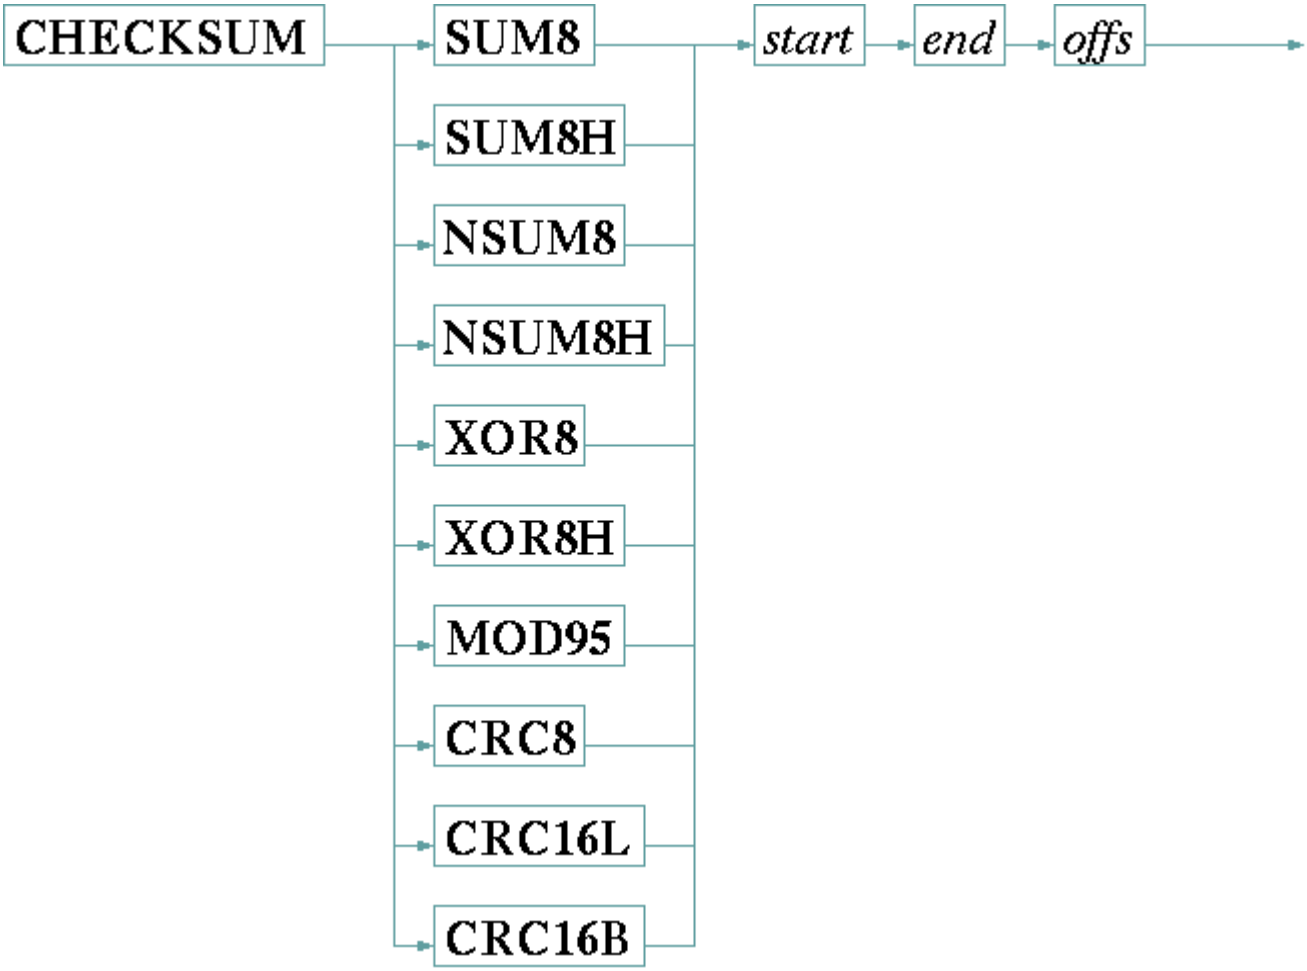
The terminating character may be specified either as a single character enclosed in double quoted or as a decimal number.

The `offset` parameter defines how many characters still have to be read or how many characters have to be cut at the end of the data to isolate the user data part of the message:

- If *offset = 0* the data read, including the termination character, is returned as the user data of the message.
- If *offset < 0* the given number of characters are cut off at the end of the data. E.g. *offset = -1* removes the termination character from the data.
- If *offset > 0* the given number of characters additionally is read and appended to the user data.

7.6.5.6 CHECKSUM

The `CHECKSUM` step reads a checksum and compares it to the checksum calculated from the message contents. If the values differ, the reception of this message is aborted and a communication fault is reported.



The parameters of this step specifier are:

SUM8	Expects a one byte checksum done by adding all bytes and truncating the sum to the lowest 8 bits.
SUM8H	Like `SUM8`, but expects the checksum coded as a 2 digit hex number.
NSUM8	Expects a one byte checksum done by adding all bytes, taking the negative value of the sum and then truncating the sum to the lowest 8 bits.
NSUM8H	Like `NSUM8`, but expects the checksum coded as a 2 digit hex number.
XOR8	Expects a one byte checksum, done by XOR-ing all specified bytes.
XOR8H	Like `XOR8`, but expects the checksum coded as a 2 digit hex number.
MOD95	Expects the one character 'modulo 95' checksum, known from the protocol used by Miteq devices (see below).
CRC8	Expects a one byte `CRC8` checksum.

CRC16L	Expects a two byte `CRC16` checksum, calculated with the ARC/LHA CRC algorithm. Expects the least significant byte first (little endian).
CRC16B	Expects a two byte `CRC16` checksum, calculated with the ARC/LHA CRC algorithm. Expects the most significant byte first (big endian).
start	The buffer position of the first character to be included in the checksum computation (0 means the first character).
end	The buffer position of the last character to be included in the checksum computation, relative to the actual position (`-1` means the last character read).
offs	The buffer position where the checksum starts, relative to the actual position (`-1` means the last character read).

The `MOD95` type checksum is computed following the formula:

$$Checksum = 32 + MOD_{95}\left[\left(\sum_{i=1}^{N} message\ byte_i\right) - (32 * N)\right]$$

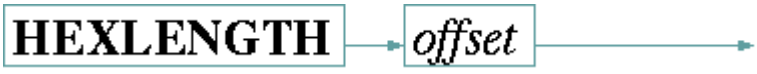
7.6.5.7 DATALENGTH

The `DATALENGTH` protocol step reads a one byte binary packet length field.

The received data length is remembered by the protocol until aUSERDATA step is encountered. The USERDATA step will read this number of bytes *minus* the offset stated with the `DATALENGTH` step.

7.6.5.8 HEXLENGTH

The DATALENGTH protocol step reads packet length field coded as a two byte hexadecimal number.



The received data length is remembered by the protocol until aUSERDATA step is encountered. The USERDATA step will read this number of bytes *minus* the offset stated with the HEXLENGTH step.

7.7 Device oriented user interface

The ***sat-nms*** software provides a so called *device oriented* user interface for each type of equipment it supports. If you double click to a device icon at the MNC user interface you

automatically get a device window for this device. The software selects the right type of device window for the device driver which is configured for this device.

To use a device oriented user interface for the device drivers you added to the software by yourself, it is necessary to extend the framework which implements the device oriented user interface. The device oriented user interface for a particular device consists of one or more parameter screens which are made specially for this device type and a number of *universal* screens which appear with almost any device. So, there are principally two steps to do:

- Define the required parameter screens for the new device type
- Define the set of screens which shall be selectable in the device window.

7.7.1 How the software finds the screens for a device

To extend the device oriented user interface, it is important to understand how device drivers and the predefined user interface windows are linked together in the ***sat-nms*** software. Principally there are three steps from the device driver to the user interface:

1. Each device driver defines a variable called `info.frame` . The device driver sets this value to the name of the frame definition it expects.
2. The user interface software - when the operator clicks to a device icon - reads the frame definition file of this name in the `dframes` subdirectory which is usually located on standard installation in `/home/satnms/dframes` .
3. The frame definition file contains the list of screens (the names of the files defining the screen layouts). The user interface software builds a card folder like window from this information.

7.7.2 Creating new screens

The software keeps the files containing the screen layouts for the device oriented user interface in a directory called `dscreens` which is usually located on standard installation in `/home/satnms/dscreens` . There is one file for each parameter screen. The screens are created with the same tool used to design customer supplied screens for the task oriented user interface.

To protect the predefined screens from being accidentally modified, the layout editing tool normally has no access to these screens. To edit a screen for the device oriented user interface, run the client with the following command line options:

Linux / on the MNC server

```
java -cp client.jar satnms3.guiconf.Configurator localhost /dscreens/...
```

where `...` is the name of the screen to edit. This opens the layout editing tool with the given file name. Please note, that the MNC server must be running at this time. The layout editing tool reads the file via the data base capabilities of the server rather than accessing the disk file directly.

Linux / on a remote machine You also may start the layout editing tool on a client computer over the LAN. At this place open a terminal sessionand enter:

```
java -cp client.jar satnms3.guiconf.Configurator [ip] /dscreens/...
```

Like above, **...** has to be replaced by the name of the screen to edit. `[ip]` stands for the IP address of the MNC server.

Windows / on a remote machine You also may start the layout editing tool on a MS Windows based client computer over the LAN. At this place open a command prompt window or create a shortcut with the following command line:

```
java -cp client.jar satnms3.guiconf.Configurator [ip] /dscreens/...**
```

Like above, `...` has to be replaced by the name of the screen to edit. `[ip]` stands for the IP address of the MNC server. If your computer does not recognize the `java`` command, try **jre** instead and check the installation of your Java Runtime Environment.

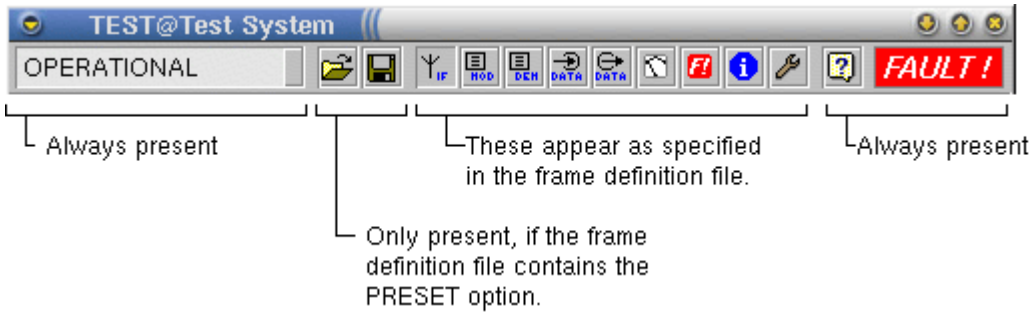
Editing the screen layout for the parameter screens is straight forward. It is recommended to use a layout similar to the existing screens. The software's user manual describes the usage of the layout editing program and introduces the types of display elements a screen may consist of.

7.7.3 Creating a 'frame' definition

The set of screens making up the window for a particular device type is called a frame. Frames are defined by text files located in the `~/dframes` directory of the software installation. To add a new frame type to the software, you have to edit such a file.

```
              PRESETS
tb-if.gif;       /dscreens/Modem-General;         General / IF parameters
tb-mod.gif;      /dscreens/Modem-TX;              Modulator parameters
tb-dem.gif;      /dscreens/Modem-RX;              Demodulator parameters
tb-dinput.gif;   /dscreens/Modem-TX-IFC;          TX interface parameters
tb-doutput.gif;  /dscreens/Modem-RX-IFC;          RX interface parameters
tb-meter.gif;    /dscreens/Modem-Measure;         Meter Readings
tb-fault.gif;    @FAULTS;                      Faults and fault mask
tb-info.gif;     @INFO;                       Device Info
tb-tool.gif;     @CONFIG;                      Maintenance
```

The example above shows a frame definition file for a SCPC satellite modem. Lines starting with a '#' are comments, they are ignored when the file is read. Below the button bar of the device window resulting from this frame definition is shown:



- The operation mode selector on the left and the help button and fault mark at the right are contained in all device screens, they need not to be specified in the frame definition file.
- The `PRESET` keyword in the third line of the frame definition file tells the software to display the buttons for parameter preset storage and retrieval in the button bar of the device window. The preset load / save buttons by default require the operator to be logged in with privilege level 100 or higher. You may append a number to the `PRESET` keyword, separated by a blanc character in order to specify the minimum privilege level for load / save preset buttons in this device window explicitly. `PRESET 150` for example makes the buttons requires privilege level 150 or higher.

The table starting at line five of the file specifies the other buttons in the tool bar and the screens bound to them. The buttons appear in the same order as the lines of the table. Each table row consists of three fields, separated by semicolon characters:

- The **first** entry selects the icon to be displayed. The following chapter shows the icons available with their file names.
- The **second** entry specifies the screen that shall be shown on a click to this button. This either is the name of a screen file (usually from the `dscreens` directory) or one of these keywords selecting a special screen:
  - **@FAULTS** : Shows the common screen listing the faults of this device.
  - **@INFO** : Shows the common screen listing the info variables for this device.
  - **@CONFIG** : Shows the common maintenance and configuration screen for this device.
  - **@SATLIST** : Shows a screen interfacing to an antenna pointing database (used by the AntennaPointing logical device)
- The **third** field defines the the help text for this button which is shown above the mouse cursor if this id hold above the button.

All device frames provided by SatService contain the @FAULTS, @INFO and @CONFIG screens in the way shown in the example.

7.8 Online Help

The ***sat-nms*** software provides a context sensitive online help based on HTML files. To make this help system easy to maintain, a simple type setting language has been defined for it. The source of the help system is contained in a couple of Markdown files containing plain text and some formatting commands. A help compiler creates all the HTML files for the online help from the sources.

With the ***sat-nms*** software there come beside a ready compiled online help also the help compiler and all sources of the help system. This enables you to extend the online help system for your needs.

You however should be aware, that the original help files (sources) are restored with each software update you install at the system. To avoid conflicts with the documentation supplied by SatService, you should modify or extend the online help only in the following situation:

1. You have written your own device driver, and you want to supply a help page for this type of equipment.

7.8.1 Help file format

Help files are now simply defined in Markdown a lightweight markup language for creating formatted text using a plain-text editor and are stored in `.md` files.

We are supporting the standard Markdown as described athttps://commonmark.org/.

If you want to have your own help files included into the online help system, please provide the new driver definition and your help files to SatService GmbH and we will automatically build the new online help with your additional files.

Attention! The old ***sat-nms*** help file format was replaced by this standardized Markdown files.

For your reference please find below this deprecated information:

So the following chapter describes the format of the source files the online manual of the software is built from.

Topic Definitions

The online manual divides the complete text into topics, where each topic is compiles to one web page. A topic is identified by it's unique four digit topic number. This number is used to build the file name of the web page and also to reference the page in hyper links.

In the source text a topic starts with a topic definition line and ends where the next topic starts. The topic definition looks like this:

.topic TTTT L The title of this topic

The keyword '.topic' must start at the very first column of the line. Further on, TTTT is the for topic number of the topic to define. L is a number in the range 1..4 defining the level of this heading in the table of contents. The remaining part of the line defines the title of the topic.

Paragraphs

The HTML text is shown by the browser as left justified text, made up to the width of the browser window. Line breaks and paragraphs do **not** appear where you type them in the source code, you have explicitly to insert line break or paragraph break commands into the source text to get these breaks in the output.

.p	Closes a paragraph. Most browsers show this as a line break followed by a half height blank line.
.br	Inserts a line break.

Both commands may appear anywhere in the line, however, usually they are placed either at the line end or in the own line.

Formatted Lists

You may typeset ordered (numbered) lists and unordered (bullet) lists in the text. Browsers usually display each list item as a paragraph, preceded by either the paragraph number or a

list item symbol. You may nest lists of both types to any depth. The help compiler simply translates the list formatting commands to HTML, it does not check if each list is properly terminated. If you produce invalid HTML code because of missing list end marks, some browsers will give strange results.

.ul	Starts a bullet list.
.ol	Starts an ordered (numbered) list
.li	Starts a list item.
.br	Inserts a line break.
.eul	Closes a bullet list.
.eol	Closes an ordered (numbered) list

Although these commands are recognized everywhere in the line, formatting lists as shown in the example below makes the source well readable.

```
.ol
  .li This is the first list item
  .li This is the second one, it contains a lot of text which does not fit in one line.
  .li The third item is a short one again.
.eol
```

Tables

Help pages may contain tables consisting of an almost arbitrary number of columns. Tables appear with a pale blue background. You have no control over the precise layout of the table, it is shown as the browser likes to display plain HTML tables with a cell background set. Because no geometry must be specified, it is very simple to define the table in the source text:

.tl	Starts a table definition
.ts	Starts the first cell of a table row
.tc	Separates a table cell from the next one in the same row
.te	Marks the end of the last table cell in a row.
.etl	Closes the table definition.

With the commands shown above, the table gets defined cell by cell, row by row. Table definitions are translated by the help compiler one by one to HTML tags. When defining a table, be careful to define the same number of cells in each row and to terminate each row properly by a **.te** command. The example below shows in which way a simple table definition should be

formatted in the source:

```
.tl
.ts cell 1/1   .tc cell 1/2   .tc cell 1/3   .te
.ts cell 2/1   .tc cell 2/2   .tc cell 2/3   .te
.ts cell 3/1   .tc cell 3/2   .tc cell 3/3   .te
.etl
```

Images / Pictures

The user manual also contains images and diagrams. Files in GIF or JPG format may be included. The image files must be located in the same directory as the other files of the online help. You find already a bunch of image files there, most of them are copies of the tool bar icons used by the software.

.i file-name	Includes an image.

If this is the only command in the line, be sure to add a single space character after the file name. This is due to a flaw of the help compiler which does not recognize the file name properly if it ends at the line end.

Pre-formatted Text

The text may include segments of 'pre-formatted' text, which the browser displays using a mono-spaced font with line breaks at the same positions as in the source. Pre-formatted text is used to include for example excerpts of configuration files.

.pre	Starts pre-formatted text
.epre	Ends pre-formatted text

The `.pre` and `.epre` commands must appear as single commands in a line, starting at the first column.

Emphasizing Text

Portions of text may be *emphasized* , **bold printed** or set in a `typewriter font` . To do this, enclose the text to highlight in curly braces and insert a letter `e` for emphasized, `b` for bold or `t` for typewrite directly after the opening brace. There must no be a space character between the opening brace and the code character. The opening and closing braces must be in the same line, nesting different hi-lighting styles is not allowed.

Cross-references / Hyper-links

You may include HTML hyper-links into the text to permit the reader to jump directly from one topic to another by a single mouse click. To insert a hyper-link, To do this, enclose the text to

hi-light in braces and insert the sequence `h####` directly after the opening brace. `####` is to be replaced by the topic number to link to. Like with the character formatting codes above, there must no be a space character between the opening brace and the `h`. The opening and closing braces must be in the same line, no nesting of braces is allowed.

Paragraph Headings

There is no special command to insert paragraph headings. The topic title is the only heading for a help page. Only this will appear in the table of contents in the printed version.

To introduce headings on a paragraph level, use a bold printed, one line paragraph instead.

Escaping Dot Commands

Words in the help text containing dots (e.g. file names) may be confused with a dot command sequence by the help compiler. Example: `MyDevice.proto` in the source file will be printed as `MyDevice` at the end of one paragraph and `roto` at the beginning of the next one. This is because the `.p` sequence in the file name is translated to a paragraph break.

The `.dot` sequence is used to escape the dot command in such a situation. Spelling the file name `MyDevice.proto` in the source produces the desired output.

Comments

You may add comments or annotations to the source text of the document which later are not shown in the manual. Lines which start with a double percent character `%%` at the first column are skipped when the file is processed by the help compiler.

Conditional Compilation

The help compiler implements a mechanism to include or skip parts of the source text depending on a couple of environment information here called *features*. The conditional compilation mechanism closely follows that one used with common programming language compilers:

%if feature	Marks the start of the documents part which only shall be included if 'feature' is present with this software installation
%else	Marks the end of `%if` branch, starts another one with the negated condition. The `%else` statement is optional
%endif	Marks the end of this `%if` or `%if` / `%else` clause.

The `%if` , `%else` and `%endif` statements must appear singly in a line and must start at the first column in the line.

The following 'features' may be tested in an `%if` clause (testing other features, always results in *not present*):

7.8.2 Rebuilding the online help

The `help` directory of the ***sat-nms*** software installation contains a shell script called makehelp. If you change to the `help` directory and call this script there, the complete online help system gets rebuilt. You should do this in one of the following cases:

- You have added a device driver to the software.
- You have edited the help file for a new device driver.
- You have edited the 'local.hlp' file.
- You installed a software update.

7.8.3 Adding help files for new devices

To display a context sensitive help for each device driver, the help system uses a separate file for each each device type, containing some information how to use and to configure the driver/device. This help topic is called if you click to the help button in a device's window.

Device driver help files use a slightly different format than the main help file does. The difference is, the a device driver help file must not contain topic definitions. One topic definition for each file is generated automatically when the help system is built.

Device driver help files are located in the `help` directory of the ***sat-nms*** software installation. The files are named like the drivers itself, but with the extension `.hlp` . The help compiler creates dummy files for missing device driver files.

The help files for the device drivers supplied by SatService all follow a common format. They first explain for which type of equipment this driver was designed for. The the button bar of the device window is described in a table. Below this the configuration/setup parameters for this device driver are explained, some device specific remarks may follow. You are encouraged to use this scheme for your customer supplied device drivers. too.

7.9 ServiceClient library

The ***sat-nms*** ServiceClient application lets you easily define virtual devices and group them to *services* which show a subset of important parameters of these devices and a summarized fault state of all devices of a service.

The ServiceClient library defines the device types the ServiceClient knows and the implementation of these devices types by ***sat-nms*** device drivers.

The ServiceClient library is an XML file which is read by the ServiceClient application at startup. You may modify this file to make the ServiceClient recognize additional ***sat-nms*** device drivers as implementation of a predefined device type or you even may define additional device types from scratch and add some implementations to them. Beside the device type definitions the XML file contains some settings which influence the GUI appearance of the ServiceClient.

The following chapters describe how to add new device types and implementations to the library and how to adapt GUI settings like the colors used for signalling the fault state of devices and services. Later chapters then describe the file format of the XML file in detail.

7.9.1 Adding new devices or device types to the library

To make the ***sat-nms*** ServiceClient recognize devices of a new type, there must be at least one `implementation` for the device type defined in the

- Devices containing multiple instances
- Fault detection
- Conditional implementation

7.9.2 Adapting the appearance of the ServiceClient

Some aspects of the ServiceClient's GUI appearance are defined in a section of the `definitions.xml` file. These are beside others the colors used to signal states like `OK`, `WARNING` or `FAULT` in the GUI. You may change these settings by editing the `definitions.xml` file, with the next start of the ServiceClient the changed settings will be used.

Chapter GUI constants later in this document gives a complet list of GUI constants which may be adapted by editing this file.

7.9.3 File format of definitions.xml

7.9.4 Device type definitions

7.9.4.1 Parameters

7.9.4.2 Implementations

7.9.5 GUI constants

The `definitions.xml` file contains a section `<gui ... </gui>` which defines a number for constant definitions which let you adapt some aspects of the program's appearance to your needs. Every definition in this sections has the form:

```
<def name="..." value="..." />
```

For each definition, `name` is a unique name for the constant, `value` is the value assigned to it. All definitions have default values which apply if the definition is not found.

Below, a table shows all known constant definitions with a description of their meaning and the default values the software assumes if the definition is not found in the `definitions.xml` file.

name	type	default	description

name	type	default	description
editorPrivilegeLevel	integer	150	The minimum privilege level an operator must have in order to edit the service configuration. For operators below this privilege level the toolbar button for the edit mode is without function.
leftPaneWidth	integer	250	The width (pixels) of the "service" screen elements which make up the left screen pane. Usually there is no need to change this except are dealing with very ling service names or comment strings which do not fit in the default width.
rightPaneWidth	integer	600	The width (pixels) of the screen elements in the right screen pane which show the parameters of a device in the service. The width of these screen elements does not automatically grow with the number of parameters shown in it, so it may be necessary to enlarge this if you are going to define new device types with many parameter in one row. The default width is sufficient to display three "wide" and one "narrow" parameters in a single row.
okBackgroundColor	color	00FF00 (green)	The background color used to signal that an element is in OK state. The service widgets on the left pane, the header of the service detailled view on the right pane and the fault indicator of each device are using this color definition. The color is expressed as a 6-digit hexadecimal RGB value defining the red, green and blue component of the color.

name	type	default	description
warningBackgroundColor	color	FFFF00 (yellow)	The background color used to signal that an element is in WARNING state. The service widgets on the left pane, the header of the service detailled view on the right pane and the fault indicator of each device are using this color definition. The color is expressed as a 6-digit hexadecimal RGB value.
faultBackgroundColor	color	FF0000 (red)	The background color used to signal that an element is in FAULT state. The service widgets on the left pane, the header of the service detailled view on the right pane and the fault indicator of each device are using this color definition. The color is expressed as a 6-digit hexadecimal RGB value.
okForegroundColor	color	000000 (black)	The text / foreground color used to signal that an element is in OK state. If you change the "okBackgroundColor", you may want to adapt the color used to the foreground as well to maintain sufficient contrast
warningForegroundColor	color	000000 (black)	The text / foreground color used to signal that an element is in WARNING state. If you change the "okBackgroundColor", you may want to adapt the color used to the foreground as well to maintain sufficient contrast
faultForegroundColor	color	FFFFFF (white)	The text / foreground color used to signal that an element is in FAULT state. If you change the "okBackgroundColor", you may want to adapt the color used to the foreground as well to maintain sufficient contrast

If you want to revert a value to its default and do not know the default setting, we recommend

to change the 'def' tag into someting other (e.g. usedefault) instead of deleting the line defining this definition. This way the name of the definition is still in the file, but due to the modified tag it will not be read.

7.10 Reference Tables

This chapter provides a number of tables with reference information which may be useful as a quick lookup for questions regarding the extension of the ***sat-nms*** software. In particular, the supplied tables are:

- Device driver keyword reference
- Protocol definition keyword reference
- Help file keyword reference
- Debugging with terminal session
- Global faults

7.10.1 Device driver keyword reference

The following table lists the keywords recognized in a device driver specification file in alphabetical order. When viewing this table online you may use the hyper-links in the description column to jump to the place where this keyword is explained in the manual.

=	Part of the syntax of a SET or BITSET statement.
ALARM	The ALARM statement defines a faults flag.
AT	Within an INPUT statement, the AT clause moves the read cursor to a certain position in the received data.
BIGENDIAN	Specifies that a WRITE or READ statement shall treat multibyte integer numbers in big endian (MSB first) byte order.
BIT	Reads a single bit from an integer number within an INPUT statement.
BITMERGE	Should no longer be used.
BITS	Specifies to write or read a number of bits with in a certain byte in a WRITE or a READ statement.
BITSET	The BITSET statement isolates a single bit from a numeric variable and assigns it to another one.
BITSPLIT	Should no longer be used.
BOOL	Defines a variable to be a boolean flag in a VAR statement.
CALL	The CALL statement calls a procedure as a subroutine.

CBER	Interprets a two character string as a bit error rate within an INPUT statement.
CHOICE	Defines a variable to be a choice list in a VAR statement.
CHOICES	Modifies a choice list variable with the RANGESET statement.
CLASS	The CLASS statement defines the Java class which does the real work. Customer supplied device drivers do not require this statement.
COMMENT	The COMMENT statement defines an identification for the driver which is reported to the user interface.
COPY	The COPY statement copies a single parameter or a complete device setup from one device to another.
CUT	Cuts a number of characters in the INPUT statement.
CYCLE	Defines the refresh cycle for a variable in the VAR statement.
DELAY	The DELAY statement pauses the driver execution for a certain time.
DISABLED	Marks a variable to be initially disabled in a VAR statement or disables a variable with the RANGESET statement.
DRATE	The DRATE statement computes an interface data rate from a symbol rate and modulation/encoding parameters.
ENABLED	Enables a variable with the RANGESET statement.
FLOAT	Defines a variable to be a floating point number in a VAR statement.
FLOAT16	Writes or reads a 16 bit floating point number with a WRITE or READ statement.
FLOAT32	Writes or reads a 32 bit floating point number with a WRITE or READ statement.
FLOAT64	Writes or reads a 64 bit floating point number with a WRITE or READ statement.
FMT	Formats a number to a string in the PRINT statement.
GET	Marks a procedure to be a GET-type one in the PROC statement.
GOTO	The GOTO statement jumps to a label in a procedure.

HEX	Interprets a string as a hexadecimal number in an INPUT statement or defines a variable to be a hexadecimal number in a VAR statement.
IF	The IF statement conditionally executes the following statement.
INCLUDE	The INCLUDE statement reads another source file.
INIT	Tells the driver to initialize a variable at power up with a certain value in the VAR statement.
INPUT	The INPUT statement reads a message from the device and parses the reply as text.
INT16	Writes or reads a 16 bit integer number with a WRITE or READ statement.
INT32	Writes or reads a 32 bit integer number with a WRITE or READ statement.
INT64	Writes or reads a 64 bit integer number with a WRITE or READ statement.
INT8	Writes or reads an 8 bit integer number with a WRITE or READ statement.
INTEGER	Defines a variable to be an integer number in a VAR statement.
INVALIDATE	The INVALIDATE statement marks a variable to be re-read in this or the next driver cycle.
LOG	The LOG statement writes a message into the event log.
MAX	Modifies the upper range limit of a numeric variable with the RANGESET statement.
MIN	Modifies the lower range limit of a numeric variable with the RANGESET statement.
OBJECT	Defines a variable to be a 'object' in a VAR statement.
OFFSET	Adds an offset to as value in a PRINT or an INPUT statement.
PRINT	The PRINT statement composes a text message/command and sends this to the device.
PROC	The PROC keyword starts a procedure definition.
PROTOCOL	The PROTOCOL statement defines the (preferred) communication protocol a driver is designed to use.

PROTOCOLPARAMETER	The PROTOCOLPARAMETER statement defines parameters to be passed to the communication protocol.
PUT	Marks a procedure to be a PUT-type one in thePROC statement.
PUTPRIORITY	Defines that the driver shall use the put priority execution scheme for PUT/GET procedures. See Topic Tweaking the processing sequence for details.
RAISECOMMFAULT	The RAISECOMMFAULT statement makes the driver to raise a communication fault.
RANGESET	The RANGESET statement modifies range properties of a variable during runtime.
READ	The READ statement gets a message from the device and parses the data as a binary data structure.
READHEX	The READHEX reads a message from the device and formats the data as a hex dump string.
READONLY	Marks a variable to be read only in aVAR statement or makes the variable read only with the RANGESET statement.
READWRITE	Makes a variable writable with the RANGESET statement.
SAVE	Tells the driver do save a variable's value on disk in theVAR statement.
SCALE	Multiplies a value with a scale factor in a PRINT or an INPUT statement.
SEND	The SEND statement sends a parameter message to another device.
SET	The SET statement assigns a value to a variable.
SETUP	Makes a variable appear in the setup menu for the device VAR statement.
SKIP	Skips whitespace characters in the INPUT statement.
SRATE	The SRATE statement computes a symbol rate from a data rate and modulation/encoding parameters.
SUBROUTINE	Marks a procedure to be a subroutine when following the PROC keyword.
SUBSCRIBE	Marks a procedure to be called if the value of a variable changes when following the PROC keyword.

SYNC	Syncs a variable, updates the value to be commanded with the value recently read back from the device.
TABLE	The TABLE statement defines a translation table.
TEXT	Defines a variable to be plain text in aVAR statement.
TRM	Cuts a string up to a given termination character in theINPUT statement.
VAR	The VAR statement defines a driver variable.
WATCH	Binds a procedure to one or more variables with thePROC statement.
WRITE	The WRITE statement composes a binary message/command and sends this to the device.
WRITEHEX	The WRITEHEX statement converts a hex dump string to a binary message, sends this to the device.
XLT	Translates a character string through a table in aPRINT or an INPUT statement.

7.10.2 Protocol definition keyword reference

The following table lists the keywords recognized in protocol definition files in alphabetic order.

ADDRESS	Outputs the device address.
ADDRESS	Reads the device address.
CHAR	Outputs a single character.
CHAR	Reads a single character.
CHECKSUM	Outputs a message checksum.
CHECKSUM	Reads a message checksum.
CLASS	Specifies the underlying protocol class.
COMMENT	Defines the protocol identification string.
DATALENGTH	Outputs a data length field (binary).
DATALENGTH	Reads a data length field (binary).
HEXLENGTH	Outputs a data length field (hex).
HEXLENGTH	Reads a data length field (hex).

PROTOCOLPARAMETER	Defines parameter to be passed to the communication protocol
RECEIVE	Starts the receive protocol step specification.
SEQUENCE	Outputs a binary message sequence number.
START	Reads a message start character.
STRING	Reads a terminated string as the user data
TRANSMIT	Starts the transmit protocol step specification.
USERDATA	Outputs the user data.
USERDATA	Reads the user data.

7.10.3 Help file keyword reference

Attention! Please remember that this is deprecated and the new file format ist Markdown.

deprecated:

The following table lists the 'dot commands' recognized by the help compiler in alphabetic order. They all are explained in the chapter ' Help file format '.

.ul	Starts a bullet list.
.ol	Starts an ordered (numbered) list
.li	Starts a list item.
.br	Inserts a line break.
.eul	Closes a bullet list.
.eol	Closes an ordered (numbered) list
.topic	Defines a topic header.
.p	Inserts a paragraph break.
.br	Inserts a line break.
.dot	Inserts a '.' (dot) character.
.tl	Starts a table definition
.ts	Starts the first cell of a table row
.tc	Separates a table cell from the next one in the same row

.te	Marks the end of the last table cell in a row.
.etl	Closes the table definition.
.i	Includes an image.
.pre	Starts pre-formatted text
.epre	Ends pre-formatted text

7.10.4 Debugging with Terminal Session

The ***sat-nms*** client provides the *terminal session window* which opens a TCP connection to Port 2000 of the MNC server. This debugging port provides several command to intercept devices and device communication and to manipulate parameters. It is also possible to access this port with any terminal program (e.g. putty with connection type `raw``).

7.10.4.1 Terminal Session Commands

Enter `?` on the command prompt to get the following short help overview:

```
---> ?
general information:
  server / faults / msg-count
messages:
  get <msg-id> / set <msg-id> <v> / loop <msg-id> <v>
message distributors:
  cdis (debug|nodebug)
  ddis (debug|nodebug)
device threads:
  threads / thread <n>
client peers:
  peers / peer <n> (view|verbose|silent|kill)
system:
  restart / shutdown / q
debug log:
  limit / nolimit
```

server

Shows information of ***sat-nms*** MNC server process including:

- state: current server state. R = normal operation
- clients: number of connected clients
- d-threads: number of devices threads (see `threads`)
- msg-rate: The `server` command outputs the current rate of updated driver variables. The rate is determined over an interval of 5 seconds. Variable update calls are counted and divided by the time that has passed since the rate was last determined. The value is

a bit too high in terms of communication to real equipment, because also the (internal) messages between logical devices are counted as well

Example:

```
---> server
state:      R
clients:    3
d-threads:  54
msg-rate:   505.69 msgs/sec
```

faults

Shows a list of all devices (one per line) and the current summary faults or warning state. Devices which are ok, just show no message text.

Example: where `HPA-2` is in WARNING state and `HPA-3` in FAULT state

```
...
HPA-1:
HPA-2: WARNING
HPA-3: Summary FAULT
S1:
S2
```

msg-count

Outputs the absolute counter readings of the messages distributed by the MNC server since startup. Starts with a high number, because all the range messages are counted at the start.

Example:

```
distributed messages
  from devices 2167806180
  to devices   2261258
```

cdis debug / cdis nodebug

Enables or disabled debug output on stdout (usually found in `/home/satnms/.panic.log`) for the client distributor. This show messages going from server to the clients (including other devices).

Attention : Enabling this output creates huge amount of date which on the disk. Do not forget to disable after testing.

Example: A beacon level (parameterId `BCRX.power`) is send to client and to a File-Recorder logical device.

```
BCRX.power distributed to satnms3.vlc.ClientPeer (176)
BCRX.power distributed to satnms3.device.FileRecorder@57576068
```

ddis debug / ddis nodebug

Enables or disabled debug output on stdout (usually found in `/home/satnms/.panic.log`) for the device distributor. This show messages going to devices (including logical devices).

Attention : Enabling this output creates huge amount of date which on the disk. Do not forget to disable after testing.

Example: A BUC is commanded to transmit (parameterId `BUC-1.tx.on`). This messages usually have their origin from user input.

Example:

```
BUC-1.tx.on distributed to tx.on ON
```

threads

Shows all list of all threads (which corresponds to the interface definition) and the current thread state. A threads / interface can have 1 or more attached devices.

Example:

```
---> threads
0   I  DT-null     (2 devices)
1   R  DT-null     (1 devices)
2   I  DT-null     (6 devices)
3   I  DT-10.10.1.13:4001(1 devices)
4   I  DT-ttyS11    (1 devices)
5   I  DT-ttyS0     (1 devices)
```

thread `n`

Show details for thread `n` . This includes (for each device attached to this thread/interface)

- device name
- device class: a Java class name if the device is hardcoded or contains hardcoded function, or satnms3.device.UniversalDriver if the driver is written completely in the ***sat-nms*** Universal Device Driver Language
- driver name
- measured cycle time: minimal/average/maximal measured cycle time in msec. This show how long the device needs to go through all GET (and PUT) procedures. It includes the idle time as configured for this interace (usually 1000 msec)
- protocol name
- protocol class: a Java class name if the protocol is hardcoded or satnms3.proto.TTYProtocol if the protocol is written in the ***sat-nms*** Universal Device

Driver Language
- interface
- response time: minimal/average/maximal measured response time for messages send to a (real) device in msec.
- thread state

Example: ***sat-nms*** LBRX Beacon Receiver with HTTP protocol

```
---> thread 19
thread 19 DT-null (I)
  device 1
    device name: BCRX-1M8
    device class: satnms3.device.UniversalDriver
    driver name: SatService-Beacon-Receiver 3.03 200430
    measured cycle time: 1124/1254/1378 msec
    protocol name: HTTP 1.01 090728
    protocol class: satnms3.proto.HTTProtocol
    interface: null
    response times: 120/157/215 msec
```

peers

Show list of all connected clients and their current state

Example: 3 connected clients from different hosts

```
---> peers
0   RI  10.10.1.143
1   RI  192.168.2.22
2   RI  192.168.2.34
```

peer `n` (view|verbose|silent|kill)

peer function	description
verbose	print all message between client and server
silent	disable verbose output
kill	close connection, drop client
view	show peer details

Example: shows details for client 1

```
---> peer 0 view
ClientPeer 0:
id:             50
destination:    10.10.1.143
input state:    R
output state:   I
queue fill:     0
uptime:         16d21h
msgs received:  297387
msgs sent:      2637717
```

Client peer input and output states:

state	description
I	Initializing
R	Reading / waiting for Data
P	Processing Data
D	Dead (Streams closed)
O	Outputting (sending Data)
S	Stopping

Example: enabled client/server verbose output where a new beacon level is send to the client and a keep alive message is exchanged between client and server (ping)

```
sent BCRX.power -71.56
sent @ping. Fri Jul 30 15:09:47 UTC 2021
got  @cpng.
```

restart

restart MNC server, similar to `satnms-stop; satnms-start` on command line or the restart button the client UI.

shutdown

shutdown MNC server. similar to to `satnms-stop` on command line

q

close terminal session

limit / nolimit

disabled log rotation of `/home/satnms/debug.log` .

Attention : Enabling this output creates huge amount of date which on the disk which will cleaned up automatically. Do not forget to disable after testing.

7.10.4.2 Device Message Commands

Within the terminal session it is possible to read and write every parameter of all devices. A typical use case is to mock parameters of equipment which is currently not connected.

command	description
get `msg-id`	show the current value of a parameter specified by `msg-id`
set `msg-id` `v`	set the value `v` of parameter specified by `msg-id`. This injects a message to the event distributor in the same way as when a user command a value from a client
loop `msg-id` `v`	set the value `v` of parameter specified by `msg-id`. This injects a message to the event distributor that looks like it was received from the equipment (response on polling)

get `msg-id`

The get command returns all parameters starting with the string in `msg-id`. If you specify a name which does not exist it returns an empty line. If `msg-id` matches more than one parameter multiple lines will be return. This allows for example to get all parameter from one device with `get BUC-1` or a subset of parameters like `get BUC-1.faults`.

Normally 2 lines return per parameters:

- the parameter itself with the current value
- the range setting of this parameter (marked with `[msg-id].R`) which describes the type range and range.
- Disabled parameters (marked with `DIS`) or parameters which where never initialized will only result in one line with the range message.

Example: Parameter BUC-1.tx.on which is a CHOICE parameter with possible values ON and OFF, currently set to ON

```
---> get BUC-1.tx.on
BUC-1.tx.on.R EnumRange (ON|OFF)
BUC-1.tx.on OFF
```

The get command recognizes a parameter `-r` which causes the command to suppress all range messages which otherwise would be included in the list.

```
---> get -r BUC-1.tx.on
BUC-1.tx.on OFF
```

The range message belonging to this paramter is not shown.

set `msg-id` `value`

The 'set' command does not produce any output (except logParameterChanges is enabled for the device). It performs also no range checking and setting values of an unknown messageId will be silently ignored.

In case of a communication fault, the driver will stop after the first INPUT statement which does not get answered by the equipment and starts from the beginning. Therefore you will not see any outgoing (PUT) commands even if you set a parameter with `set` until you stop the driver cycle aka polling (see below).

Example: switch BUC transmit to ON

```
---> set BUC-1.tx.on OFF
000000 2021-07-30 16:07:50 2021-07-30 16:07:50   I BUC-1 tx.on changed to 'OFF' by debug
```

loop `msg-id` `value`

A loop commands simulates that the device receives a message from equipment. So it looks like, that the equipment response to polling. With this command you can mock e.g. read-only values to display something useful even if you have no equipment connected.

But remember, values set with the `loop` command will be overwritten by next successful polling result (if there is communication to the equipment)

Example: set the output power of an BUC to 162 (Watt). On first `get` BUC-1.meas.fwdPwr is not initialized, but after `loop` ing 162 to the device it show this new value on the next `get`

```
---> get BUC-1.meas.fwdPwr
BUC-1.meas.fwdPwr.R IntegerRange R/O (0 .. 0)

---> loop BUC-1.meas.fwdPwr 162

---> get BUC-1.meas.fwdPwr
BUC-1.meas.fwdPwr 162
BUC-1.meas.fwdPwr.R IntegerRange R/O (0 .. 0)
```

verbose mode

Enable *verbose mode* for a device to follow all communication between MNC server and equipment *Verbose mode* could be enabled in the device setup page of each device or in the terminal session with `set [DEVICENAME].verbose true`.

Example: Beacon Receiver with HTTP protocol. Parameter BCRX.threshold is read from the device with the command `/rmt?thrh=?`

```
---> set BCRX.verbose true
tx(BCRX): /rmt?thrh=?
rx(BCRX): thrh=-90.00
  BCRX.threshold=-90.00
```

In addition you can enable *dump mode* for a device to print full communication between MNC's server and equipment even if it does not match with the required protocol structure with `set [DEVICENAME].dump true`.

Attention : Enabling this output creates huge amount of date which on the disk so do not forget to disable after testing.

stop polling cycle

You can stop the driver cycle with the following command in the terminal session: `set [DEVICENAME].cycle true`. Re-enable polling with `set [DEVICENAME].cycle false` or a restart of the MNC server.

Example: disable polling and set a value on a not connected device. After disabling polling the device tries one more time to communicate (`tx(BUC-1): GET ...`) but does not expect a response anymore. Device state switches to Communication OK.

```
---> set BUC-1.cycle false
tx(BUC-1): GET 1.3.6.1.4.1.2566.127.1.5.10.1.1.14.1.2.0 (FAILED)
000000 2021-07-30 15:52:20 2021-07-30 15:52:20   I BUC-1 past 0m17s Communication OK.
000000 2021-07-30 15:52:20 2021-07-30 15:52:20   I BUC-1 OK.
```

Now you can issue a `set` command (or send commands via Client UI) and the corresponding PUT procedures will be executed. Of course you will still not get any response from the equipment, so the Communication Fault will be issued.

```
---> set BUC-1.tx.on OFF
000000 2021-07-30 15:57:46 2021-07-30 15:57:46   I BUC-1 tx.on changed to 'OFF' by debug
tx(BUC-1): SET 1.3.6.1.4.1.2566.127.1.5.10.1.2.1.3.1.0 I 1 (FAILED)
000000 2021-07-30 15:57:55 2021-07-30 15:57:55   I BUC-1 past 2m57s Communication OK.
000000 2021-07-30 15:57:55 2021-07-30 15:57:55   I BUC-1 OK.
```

7.10.5 Global faults

The M&C software knows two global faults flags indicating fault conditions which are not linked do devices or subbsystems:

SYSTEM.fault

indicates some sort of general fault, mostly faults occurring during the initialization phase of the M&X. SYSTEM.fault may be one of "OK." and "Summary FAULT". Which condition caused

the fault is listed in the event log. A "RESET" to the SYSTEM device clears this fault.

SUMMARY.fault

summarizes the the faults of all devices in the M&C. SUMMARY.fault knows two states, 'FAULT' and 'OK.'. It turns to 'FAULT' if at least one device in the M&C shows a fault.

8 API Reference

This document describes the sat-nms WebGUI backend server API which is used by the Web front end of the software and also may be used to control a sat-nms M&C in a programmatic way.

Quick access links to the main sections of the document:

- HTTPS Communication and OAuth2 Authentication
- API End Points
- WebSocket Communication
- Data Models
- Satellite Database

8.1 HTTPS Communication and OAuth2 Authentication

The sat-nms WebGUI backend server uses HTTPS for all communication. Unsecured HTTP calls are not accepted. In most cases a non-standard port number is used by the server, details about the port and also about the certificate provided by the server may vary for every installation of the software.

The backend server uses OAuth2 for authorization. It may be configured to accept JWTs issued by an external provider. In parallel the backend server provides a service for obtaining and renewing access tokens as well.

8.2 API End Points

This section describes the API end points provided by the sat-nms WebGUI backend server. The end point descriptions appear in an order which groups related functions. An alphabetic list of all end points is shown below.

- /api/v1/activebackend
- /api/v1/acutargets
- /api/v1/antennas
- /api/v1/applypreset
- /api/v1/backendinfo
- /api/v1/channels
- /api/v1/collectpreset
- /api/v1/dbstate
- /api/v1/dbversion
- /api/v1/debug
- /api/v1/devicesetup
- /api/v1/dframes
- /api/v1/documents
- /api/v1/drivers
- /api/v1/dscreens

- /api/v1/eventack
- /api/v1/eventreport
- /api/v1/filerecordings
- /api/v1/filerecordersettings
- /api/v1/globalSettings
- /api/v1/healthcheck
- /api/v1/inventory
- /api/v1/logout
- /api/v1/macros
- /api/v1/makewebsocket
- /api/v1/mnclist
- /api/v1/peek
- /api/v1/playmacro
- /api/v1/poke
- /api/v1/preferredprotocols
- /api/v1/presets
- /api/v1/presetvars
- /api/v1/devicevars
- /api/v1/protocols
- /api/v1/redundancy
- /api/v1/restart
- /api/v1/satdetails
- /api/v1/satellites
- /api/v1/satoperators
- /api/v1/schedule
- /api/v1/streamkeys
- /api/v1/subscribe
- /api/v1/tleimport
- /api/v1/thumbnail
- /api/v1/trackmem
- /api/v1/treeview
- /api/v1/uscreens
- /api/v1/user
- /api/v1/users
- /api/v1/userSettings
- /healthcheck
- /token

8.2.1 /token

The /token API call requests an access token from the server which can be used to authorize subsequent API calls.

All API calls except /token require a valid access token (JWT) to be passed with the header of the request as a "Authorization: Bearer ..." header or the server will abort with a 401 NOT AUTHENTICATED error.

Supported HTTP methods: POST

POST /token

Requests an access token for the user specified with the parameters added to this call. The parameter to this request must be passed as HTML form style parameters (application/x-www-form-urlencoded). The same end point is used to get a new and to renew an existing token.

Parameters:

Name	Value
username	The name of the user to log in. Must be a valid user name known to the sat-nms M&C application.
password	The password supplied by the user for login (clear text).
grant_type	One of 'password' or 'refresh_token'
refresh_token	A valid refresh token, making the backend to reply with a new version of the existing access token linked to this refresh token.

The *grant_type* parameter is mandatory, if it is set to 'password' the parameters *password* and *username* are requires as well. If *grant_type* is set to 'refresh_token', the parameter *refresh_token* is mandatory as well.

On success the API call returns a TokenReply document containing beside other information the access token and a refresh token to renew the access token.

Return Codes:

Code	Description
200	OK, login was successful. A TokenReply document is replied.
400	*grant_type* is neiter 'password' nor 'refresh_token'
401	Login failed. In this case a ApiError document is returned, describing details of the error. This happens either with *grant_type*='password' and invalid credentials or with *grant_type*='refresh_token' and an invalid refresh token.

8.2.2 /api/v1/logout

Logs out the currently logged in user.

Supported HTTP methods: POST

POST /api/v1/logout

Logs out the currently logged in user. Requires a valid access token to be passed with the request header to identify the session to be terminated. In fact, this call does not logout all

open sessions of a given user, it terminates exactly one session which is referenced by the token.

Parameters: none

Return Codes:

Code	Description
204	OK, logout was successful. No payload data follows.

8.2.3 /healthcheck

This API call can be used to check if the backend server responds to API calls. It works without being logged in.

Supported HTTP methods: GET,HEAD,OPTIONS

GET /healthcheck

Returns an Dictionary document listing some basic status information about the backend server. As this API call is with public access, it returns only a limited set of information.

The Dictionary document returned contains the following keys with its values:

Key	Description
PRODUCT	The name of this product
WEBSITE	The SatService website URL
VERSION	The software version actually running
SERIALNO	The software serial number

Parameters: none

Return Codes:

Code	Description
200	OK, the Dictionary with the status information is returned as payload.

8.2.4 /api/v1/user

Delivers some information about the user currently logged in. Returns aUserProperties document describing the user. This document contains -- beside other information -- the

privilege level of the user which must be known to decide which user interface elements must be shown in a read-only way because the user is not authorized to change these parameter (but he may read them if logged in).

This API end point also may be used with PUT to change the password of the actually logged in user.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/user

Returns a UserProperties document describing the currently logged in user.

Expected Payload: none

Replied Payload: a UserProperties document with information about the user who issued this call.

Parameters: none

Return Codes:

Code	Description
200	OK, returns a UserProperties document describing the currently logged in user. If no information about the currently logged in user is available, a dummy Document describing a user with the name 'unknown' and the privilege level '0' is returned.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/user

Changes the password of the user issuing this call. Returns the (updated)UserProperties for the currently logged in user.

Expected Payload: a UserProperties document containing the new password for the actual user. All other fields of the the document are ignored.

Replied Payload: a UserProperties document with the updated user information.

Parameters: none

Return Codes:

Code	Description
200	OK, returns a UserProperties with the updated data for the actually logged in user.

Code	Description
401	not logged in. In this case a ApiError document is returned, describing details of the error.

8.2.5 /api/v1/users

Reads or writes the list of users known to the backend. When editing the user list, the list must be read with a GET and later sent back with a PUT with all fields in each UserProperties record.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/users

Gets a UserList document containing the list of all known users.

Expected Payload: none

Replied Payload: a UserList document containing the list of all known users.

Parameters: none

Return Codes:

Code	Description
200	OK, returns a UserList containing the list of all known users.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/users

Send a UserList document containing the list of all known users to the backend. The UserList replaces the previous one. Already logged in users remain logged in, even if they are deleted from the list or if their password was changed.

Expected Payload: The UserList document to write.

Replied Payload: The UserList document echoed back.

Parameters: none

Return Codes:

Code	Description
200	OK, returns the written UserList echoed back.

Code	Description
400	cannot change the password. Probably the user logged in by LDAP. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

8.2.6 /api/v1/mnclist

Delivers a list containing some information about the M&C systems managed by the backend. Returns a MncList document containing this list.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/mnclist

Returns a MncList document containing the list of managed M&C systems and their properties.

Parameters: none

Return Codes:

Code	Description
200	OK, returns a MncList document containing the list of managed M&C systems.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

8.2.7 /api/v1/activebackend

Delivers an ActiveBackend document showing the name of the backend which is actually considered to be active for M&C redundancy switching. Also permits to change this using a PUT call.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/activebackend

Returns an ActiveBackend document showing the name of the backend which is actually considered to be active for M&C redundancy switching.

Parameters: none

Expected Payload: none.

Replied Payload: Returns an ActiveBackend document showing the name of the backend which is actually considered to be active for M&C redundancy switching.

Return Codes:

Code	Description
200	OK, returns the expected document
401	not logged in. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/activebackend

Sets the name of the of the backend which is actually considered to be active for M&C redundancy switching.

Parameters: none

Expected Payload: An ActiveBackend document containing the name of the backend which shall be considered to be active for M&C redundancy switching.

Replied Payload: Returns an ActiveBackend document showing the name of the backend which is actually considered to be active for M&C redundancy switching.

Return Codes:

Code	Description
200	OK, the name of the active backend has been updated. Returns the expected document
401	not logged in. In this case a ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

8.2.8 /api/v1/peek

Reads ('peeks') the Parameter or Range definition addressed by {messageId} from the backend's message cache. If no such message is present in the cache, the M&C server is asked to deliver the message. The API call waits up to 3 seconds for the M&C server to answer, then a 404 error is returned. Peeking parameters is a very inefficient way to get a parameter value. It only should be used if a parameter value is required only once (without subsequent updates) or for testing purposes. Section WebSocket Communication describes the subscription model using STOMP/websockets which is the preferred way to read/update parameters in the UI.

The {messageId} supplied to /api/v1/peek must be a complete message identifier consisting of M&C-, device- and parameter-ID.

The document returned on success is either a Parameter or a Range, depending on the {messageId} supplied. For details about messages and message identifiers, see section

Message later in this document.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/peek/{messageId}

Returns a Message document describing the requested parameter.

Parameters:

Parameter	Description
messageId	The requested messageId. Must be a complete message identifier consisting of M&C-, device- and parameter-ID.

Return Codes:

Code	Description
200	OK, returns a Message document describing the requested parameter.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no parameter with the given messageId exists. In this case a ApiError document is returned, describing details of the error.

8.2.9 /api/v1/poke

Writes ('pokes') a Parameter or Range message to the M&C server. The message to be written must be supplied as POST data.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/poke

Expects exactly one Parameter document as POST data. This creates and distributes the message on the M&C server addressed by the M&C identifier contained in the supplied message. This does not check if the specified destination exists. Messages sent to non-existing destinations are silently ignored, also result in a 201 response.

Parameters: none

Return Codes:

Code	Description
201	Success, echoes the message created.

Code	Description
401	not logged in. In this case a ApiError document is returned, describing details of the error.

8.2.10 /api/v1/makewebsocket

Creates a new websocket to connect to. A unique ID is generated for this websocket and returned as a WebsocketId document in the call's response body.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/makewebsocket

Creates a new websocket to connect to. A unique ID is generated for this websocket and returned as a WebsocketId document in the call's response body.

The WebsocketId is required to open the socket itself and for all subscribe / unsubscribe operations on this websocket. See section Websocket Communication for details about how to open a websocket.

Parameters: none

Return Codes:

Code	Description
201	Success, delivers the ID of the created websocket in the response body (data model WebsocketId).
401	not logged in. In this case a ApiError document is returned, describing details of the error.

8.2.11 /api/v1/subscribe

Subscribes or unsubscribes the delivery of one or more message IDs over the websocket connection. Whether to subscribe or unsubscribe is defined by the HTTP method.

Supported HTTP methods: POST, DELETE, HEAD, OPTIONS

POST /api/v1/subscribe/{websocketId}/{messageId}

Subscribes for the reception of messages with the given messageId over the websocket identified by websocketId. The requested message and all subsequent updates are sent over the websocket connection.

Returns a SubscribeList with the response body containing the message IDs which have been successfully subscribed (in this case of a single subscription the list contains either one or no message IDs).

The API call does not check if the remote M&C system can deliver a message with the given ID. Messages may become available later, this is a common situation.

Parameters:

Parameter	Description
websocketID	Identifies the websocket to send the message and subsequent updates to. See section Websocket Communication how to obtain a websocketID and how to open a websocket.
messageId	Identifies the message / parameter to subscribe. Must be a complete sat-nms message identifier including the M&C ID.

Return Codes:

Code	Description
201	Success, a SubscribeList is returned with the response body containing the (single) subscribed message ID.
401	Not logged in. In this case a ApiError document is returned, describing details of the error.
403	Invalid websocketId. The websocketId referenced in the URL either does not exist or the session which sent the request does not own this websocket. An empty SubscribeList is returned with the response body.

POST /api/v1/subscribe/{websocketId}

Subscribes for the reception of messages of multiple message IDs over a websocket. This variant of the API call expects a SubscribeList data object in the request body. This data object contains the message IDs to subscribe for.

The subscription requests are forwarded and are checked if successful one by one. The API call returns a SubscribeList in the response body containing the message IDs which have been successfully subscribed.

The API call does not check if the remote M&C system can deliver messages with the given IDs. Messages may become available later, this is a common situation.

Parameters:

Parameter	Description
websocketID	Identifies the websocket to send the message and subsequent updates to. See section Websocket Communication how to obtain a websocketID and how to open a websocket.

Return Codes:

Code	Description
201	Success, a SubscribeList is returned with the response body containing the subscribed message IDs.
401	Not logged in. In this case a ApiError document is returned, describing details of the error.
403	Invalid websocketId. The websocketId referenced in the URL either does not exist or the session which sent the request does not own this websocket. An empty SubscribeList is returned with the response body.

DELETE /api/v1/subscribe/{websocketId}/{messageId}

Unsubscribes the reception of messages with the given messageId over the websocket identified by websocketId.

Returns a SubscribeList with the response body containing the message IDs which have been successfully unsubscribed (in this case the list contains either one or no message IDs).

The API call does not check if there is a subscription pending for the given parameters. If a subscription is canceled which never has been done or which has been unsubscribed before, this is silently ignored.

Parameters:

Parameter	Description
websocketID	Identifies the websocket to unsubscribe. See section Websocket Communication how to obtain a websocketID and how to open a websocket.
messageId	Identifies the message / parameter to unsubscribe. Must be a complete sat-nms message identifier including the M&C ID.

Return Codes:

Code	Description
200	Success, a SubscribeList is returned with the response body containing the (single) unsubscribed message ID.
401	Not logged in. In this case a ApiError document is returned, describing details of the error.

Code	Description
403	Invalid websocketId. The websocketId referenced in the URL either does not exist or the session which sent the request does not own this websocket. An empty SubscribeList is returned with the response body.

DELETE /api/v1/subscribe/{websocketId}

Unsubscribes the reception of multiple message IDs over a websocket. This variant of the API call expects a SubscribeList data object in the request body. This data object contains the message IDs to unsubscribe.

The subscription requests are forwarded and are checked if successful one by one. The API call returns a SubscribeList in the response body containing the message IDs which have been successfully subscribed.

The API call does not check if there are subscriptions pending for the given message IDs. If a subscription is canceled which never has been done or which has been unsubscribed before, this is silently ignored.

Parameters:

Parameter	Description
websocketID	Identifies the websocket to unsubscribe. See section Websocket Communication how to obtain a websocketID and how to open a websocket.

Return Codes:

Code	Description
201	Success, a SubscribeList is returned with the response body containing the unsubscribed message IDs.
401	Not logged in. In this case a ApiError document is returned, describing details of the error.
403	Invalid websocketId. The websocketId referenced in the URL either does not exist or the session which sent the request does not own this websocket. An empty SubscribeList is returned with the response body.

8.2.12 /api/v1/uscreens

Gives access to the user defined screen definitions stored on the primary M&C. Screen definitions may be listed, read or written with this call.

Supported HTTP methods: GET, POST, HEAD, OPTIONS

GET /api/v1/uscreens

Returns a list of all available uscreens.

Parameters: none.

Expected Payload: none.

Replied Payload: Returns an ItemList containing the names of all available user screens. The list is read from the primary M&C.

Return Codes:

Code	Description
200	OK, returns an ItemList containing the names of all available user screens.
400	the primary M&C is offline, the list cannot be read. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

GET /api/v1/uscreens/{name}

Returns a ScreenDefinition document describing the requested screen. The screen definition is read from the primary M&C.

Parameters:

Parameter	Description
name	The name of the screen to load. Please note, that screen names are case sensitive, the name must match exactly to be loaded.

Expected Payload: none.

Replied Payload: Returns a ScreenDefinition document describing the requested screen.

Return Codes:

Code	Description
200	OK, returns a ScreenDefinition document describing the requested screen.
400	the primary M&C is offline, the screen cannot be read. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

Code	Description
404	no screen definition with the given name exists. In this case a ApiError document is returned, describing details of the error.

POST /api/v1/uscreens/{name}

Stores a ScreenDefinition at the primary M&C. If the screen already exists, it gets overwritten.

Parameters:

Parameter	Description
name	The name of the screen to store. Screen definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: The ScreenDefinition to store.

Replied Payload: Echoes back the written ScreenDefinition.

Return Codes:

Code	Description
200	OK, echoes back the written ScreenDefinition.
400	the primary M&C is offline, the screen cannot be written. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

DELETE /api/v1/uscreens/{name}

Deletes a ScreenDefinition at the primary M&C.

Parameters:

Parameter	Description
name	The name of the screen to delete. Screen definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the screen has been deleted.
400	the primary M&C is offline, the screen cannot be deleted. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	not found. No screen of this name exists. In this case aApiError document is returned, describing details of the error.

8.2.13 /api/v1/dscreens

Gives access to the device screen definitions stored on the primary M&C. Screen definitions may be listed, read or written with this call.

Supported HTTP methods: GET, POST, HEAD, OPTIONS

GET /api/v1/dscreens

Returns a list of all available dscreens. The list is read from the primary M&C.

Parameters: none.

Expected Payload: none.

Replied Payload: Returns an ItemList containing the names of all available device screens.

Return Codes:

Code	Description
200	OK, returns an ItemList containing the names of all available device screens.
400	the primary M&C is offline, the list cannot be read. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

GET /api/v1/dscreens/{name}

Returns a ScreenDefinition document describing the requested screen. The screen is read from the primary M&C.

Parameters:

Parameter	Description

Parameter	Description
name	The name of the screen to load. Please note, that screen names are case sensitive, the name must match exactly to be loaded.

Expected Payload: none.

Replied Payload: Returns a ScreenDefinition document describing the requested screen.

Return Codes:

Code	Description
200	OK, returns a ScreenDefinition document describing the requested screen.
400	the primary M&C is offline, the screen cannot be read. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no screen definition with the given name exists. In this case a ApiError document is returned, describing details of the error.

POST /api/v1/dscreens/{name}

Stores a ScreenDefinition at the primary M&C. If the screen already exists, it gets overwritten.

Parameters:

Parameter	Description
name	The name of the screen to store. Screen definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: The ScreenDefinition to store.

Replied Payload: Echoes back the written ScreenDefinition.

Return Codes:

Code	Description
200	OK, echoes back the written ScreenDefinition.
400	the primary M&C is offline, the screen cannot be written. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

DELETE /api/v1/dscreens/{name}

Deletes a ScreenDefinition at the primary M&C.

Parameters:

Parameter	Description
name	The name of the screen to delete. Screen definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the screen has been deleted.
400	the primary M&C is offline, the screen cannot be deleted. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	not found. No screen of this name exists. In this case aApiError document is returned, describing details of the error.

8.2.14 /api/v1/dframes

Gives access to the device frame definitions stored on the primary M&C. Device frame definitions may be listed, read or written with this call.

Supported HTTP methods: GET, POST, HEAD, OPTIONS

GET /api/v1/dframes

Returns a list of all available device frame definitions. The list is read from the primary M&C.

Parameters: none.

Expected Payload: none.

Replied Payload: Returns an ItemList containing the names of all available device frame definitions.

Return Codes:

Code	Description
200	OK, returns an ItemList containing the names of all available device frame definitions.
400	the primary M&C is offline, the list cannot be read. In this case aApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

GET /api/v1/dframes/{name}

Returns a DeviceFrameDefinition document describing the requested frame. The frame definition is read from the primary M&C.

Parameters:

Parameter	Description
name	The name of the frame definition to load. Please note, that frame names are case sensitive, the name must match exactly to be loaded.

Expected Payload: none.

Replied Payload: Returns a DeviceFrameDefinition document describing the requested frame.

Return Codes:

Code	Description
200	OK, returns a DeviceFrameDefinition document describing the requested frame.
400	the primary M&C is offline, the frame definition cannot be read. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no frame definition with the given name exists. In this case aApiError document is returned, describing details of the error.

POST /api/v1/dframes/{name}

Stores a DeviceFrameDefinition at the primary M&C. If the frame definition already exists, it gets overwritten.

Parameters:

Parameter	Description
name	The name of the frame to store. DeviceFrame definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: The DeviceFrameDefinition to store.

Replied Payload: Echoes back the written DeviceFrameDefinition.

Return Codes:

Code	Description
200	OK, echoes back the written DeviceFrameDefinition.
400	the primary M&C is offline, the frame definition cannot be written. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

DELETE /api/v1/dframe/{name}

Deletes a DeviceFrameDefinition at the primary M&C.

Parameters:

Parameter	Description
name	The name of the frame definition do delete. DeviceFrame definition names may consist of the characters A-Z, a-z, 0-9 and the hyphen character.

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the device frame has been deleted.
400	the primary M&C is offline, the frame definition cannot be deleted. In this case a ApiError document is returned, describing details of the error.
401	not logged in. In this case a ApiError document is returned, describing details of the error.

Code	Description
404	not found. No device frame of this name exists. In this case aApiError document is returned, describing details of the error.

8.2.15 /api/v1/macros

Permits to load and save sat-nms macro definitions as well as to read the list of macros defined on a given M&C.

Supported HTTP methods: GET, PUT, DELETE, HEAD, OPTIONS

GET /api/v1/macros/{mncName}

Returns an ItemList document containing the list of macros defined on the given M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the macro list shall be loaded.

Return Codes:

Code	Description
200	OK, returns an ItemList containing the requested macro list.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case aApiError document is returned, describing details of the error.

GET /api/v1/macros/{mncName}/{macroName}

Returns a Macro document containing the requested macro.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the macro shall be loaded.
macroName	The name of the macro to load.

Return Codes:

Code	Description
200	OK, returns a Macro containing the requested macro.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no macro with the requested name. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/macros/{mncName}/{macroName}

Saves a macro on the given M&C. Expects Macro document containing the macro text to save as request body. The *name* field in the Macro document will be ignored, the macro will be saved under the name given in the URL. As every PUT request, this will either overwrite an existing macro with this name or create a new macro definition at the M&C if no macro with this name exists.

Parameters:

Parameter	Description
mncName	The name of the M&C on which the macro shall be saved.
macroName	The name of the macro to save.

Return Codes:

Code	Description
200	OK, returns the Macro containing the saved macro. This will have the *name* field set the name under which the macro actually has been saved.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

DELETE /api/v1/macros/{mncName}/{macroName}

Deletes a macro at the given M&C.

Parameters:

Parameter	Description

Parameter	Description
mncName	The name of the M&C on which the macro shall be deleted.
macroName	The name of the macro to delete.

Return Codes:

Code	Description
200	OK, returns the Macro containing the deleted macro.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no macro with the requested name. In this case a ApiError document is returned, describing details of the error.

8.2.16 /api/v1/playmacro

Executes a macro on a given M&C.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/playmacro/{mncName}

Executes the referenced macro. Expects the macro to play as aMacro body, delegates the request to the M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C at which the macro shall be loaded and executed.

Return Codes:

Code	Description
200	OK, returns the Macro containing the executed macro.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	the M&C with the given name does nit exist. In this case aApiError document is returned, describing details of the error.

POST /api/v1/playmacro/{mncName}/{macroName}

Executes the referenced macro. Expects no request body, simply delegates the request to the M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C at which the macro shall be loaded and executed.
macroName	The name of the macro to execute.

Return Codes:

Code	Description
200	OK, returns the Macro containing the executed macro.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no macro with the requested name. In this case a ApiError document is returned, describing details of the error.

8.2.17 /api/v1/presets

Permits to load and save sat-nms device preset definitions as well as to read the list of presets defined on a given M&C.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/presets/{mncName}

Returns an ItemList document containing the list of preset directories found on the given M&C. This is the list of device drivers which have at least one preset saved on this M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the preset directory list shall be loaded.

Return Codes:

Code	Description

Code	Description
200	OK, returns an ItemList containing the requested preset directory list.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

If the given M&C name exists, but there are no presets stored at all, the request returns 200 OK and an empty list.

GET /api/v1/presets/{mncName}/{driverName}

Returns an ItemList document containing the list of presets defined this device driver on the given M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the preset list shall be loaded.
driverName	The name of the device driver for which the preset list shall be loaded.

Return Codes:

Code	Description
200	OK, returns an ItemList containing the requested preset list.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

If the given M&C name exists, but there are no presets stored for the driver type, the request returns 200 OK and an empty list.

GET /api/v1/presets/{mncName}/{driverName}/{presetName}

Returns a DevicePreset document containing the requested preset.

Parameters:

Parameter	Description

Parameter	Description
mncName	The name of the M&C from which the preset shall be loaded.
driverName	The name of the device driver for which the preset shall be loaded.
presetName	The name of the preset to load.

Return Codes:

Code	Description
200	OK, returns a DevicePreset containing the requested preset.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no preset with the requested driver/name combination. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/presets/{mncName}/{driverName}/{presetName}

Saves a preset on the given M&C. Expects DevicePreset document containing the preset text to save as request body. The *name* and *driver* fields in the DevicePreset document will be ignored, the preset will be saved under the driver / name given in the URL. As every PUT request, this will either overwrite an existing preset with this name or create a new preset definition at the M&C if no preset with this name exists.

Parameters:

Parameter	Description
mncName	The name of the M&C on which the preset shall be saved.
driverName	The name of the device driver for which the preset shall be saved.
presetName	The name of the preset to save.

Return Codes:

Code	Description
200	OK, returns the DevicePreset containing the saved preset. This will have the *name* and *driver* fields set the values under which the preset actually has been saved.

Code	Description
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

DELETE /api/v1/presets/{mncName}/{driverName}/{presetName}

Deletes a preset from the given M&C. Expects no request body.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the preset shall be deleted.
driverName	The name of the device driver for which the preset shall be deleted.
presetName	The name of the preset to delete.

Return Codes:

Code	Description
200	OK, returns the DevicePreset containing the deleted preset.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists or no device preset with that name / device driver could be found. In this case a ApiError document is returned, describing details of the error.

8.2.18 /api/v1/applypreset

Applies a preset on a given M&C.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/applypreset/{mncName}/{deviceName}

Applies a preset to the given device. Expects a DevicePreset as request body, then delegates the request to the M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C at which the preset shall be applied.
deviceName	The name of the device to apply the preset to.

Return Codes:

Code	Description
200	OK, returns the DevicePreset containing the applied preset.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

POST /api/v1/applypreset/{mncName}/{driverName}/{deviceName}/{presetName}

Applies the referenced preset to the given device. Expects no request body, simply delegates the request to the M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C at which the preset shall be applied.
driverName	The name of the device driver for which the preset shall be applied.
deviceName	The name of the device to apply the preset to.
presetName	The name of the preset to apply.

Return Codes:

Code	Description
200	OK, returns the DevicePreset containing the applied preset.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no driver/device/preset with the requested name. In this case a ApiError document is returned, describing details of the error.

8.2.19 /api/v1/collectpreset

Collects a preset on a given M&C. This tells the referenced device to collect its settings into a preset and to store this preset in the M&C with the given name.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/collectpreset/{mncName}/{driverName}/{deviceName}/{presetName}

Collects a preset on a given M&C. This tells the referenced device to collect its settings into a preset and to store this preset in the M&C with the given name. Expects no request body, simply delegates the request to the M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C at which the preset shall be collected.
driverName	The name of the device driver for which the preset shall be collected.
deviceName	The name of the device to collect the preset from.
presetName	The name of the preset to store.

Return Codes:

Code	Description
200	OK, returns the DevicePreset containing the collected preset.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either M&C with the given name exists or at the known M&C there exists no device with the requested name. In this case a ApiError document is returned, describing details of the error.

8.2.20 /api/v1/presetvars

Delivers the list of driver variable which may be stored in a preset for a given device driver.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/vi/presetvars/{mncName}/{driverName}

Returns a PresetVars document containing the requested list of preset-storable variables. The backend reads the device driver *driverName.device* from the given M&C, compiles the driver text and selects the preset storable variables from the compiled list. The returned PresetVars

document contains the Range definitions for all variables of the driver which may appear in a device preset. The *messageId* field in each Range object is set to the name of the variable.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the variable list shall be loaded.
driverName	The name of the device driver for which the variable list shall be evaluated.

Return Codes:

Code	Description
200	OK, returns a PresetVars document containing the requested variable list.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either no M&C with the given name exists, or at the known M&C there exists no device driver with the given name. In this case a ApiError document is returned, describing details of the error.

8.2.21 /api/v1/devicevars

Delivers the list of all variables a device defines

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/vi/devicevars/{mncName}/{deviceName}

Returns a DeviceVars document containing the requested list of variables. The backend evaluates the driver for the given device, compiled the device driver and gets the variable list from this. The returned DeviceVars document contains the Range definitions for all variables of the driver which may appear in a device preset. The *messageId* field in each Range object is set to the name of the variable.

The API call returns the variable list as it exists at compile time at system startup. Changes made dynamically to the list of variables or to some variable ranges are not contained in the list

Parameters:

Parameter	Description
mncName	The name of the M&C from which the variable list shall be loaded.

Parameter	Description
deviceName	The name of the device for which the variable list shall be evaluated.

Return Codes:

Code	Description
200	OK, returns a PresetVars document containing the requested variable list.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	either no M&C with the given name exists, or at the known M&C there exists no device driver with the given name. In this case a ApiError document is returned, describing details of the error.

8.2.22 /api/v1/schedule

Permits to load and save the macro scheduler's schedule at a given M&C.

When subscribing for a '.SYSTEM.schedule' parameter of a M&C, the front end receives a message which indicates 'an updated schedule is available' instead of sending the bulky schedule itself over the websocket connection.

After the front end received this message, it can use the /api/v1/schedule API call to retrieve the schedule as a Schedule data object.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/schedule/{mncName}

Returns a Schedule document containing the actual system schedule from this M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C from which the schedule shall be loaded.

Return Codes:

Code	Description
200	OK, returns a Schedule document containing the requested schedule.

Code	Description
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

PUT /api/v1/schedule/{mncName}

Overwrites the system schedule at the given M&C. Expects a Schedule document containing new schedule to set.

Parameters:

Parameter	Description
mncName	The name of the M&C on which the preset shall be saved.

Return Codes:

Code	Description
200	OK, returns the Schedule containing the saved schedule.
401	not logged in. In this case a ApiError document is returned, describing details of the error.
404	no M&C with the given name exists. In this case a ApiError document is returned, describing details of the error.

8.2.23 /api/v1/healthcheck

This API call delivers some status information about the running backend server. Unlike the version with public access, this version of the health check contains the complete set of information.

Supported HTTP methods: GET,HEAD,OPTIONS

GET /api/v1/healthcheck

Returns an Dictionary document listing some status information about the backend server.

The Dictionary document returned contains the following keys with its values:

Key	Description
PRODUCT	The name of this product

Key	Description
WEBSITE	The SatService website URL
VERSION	The software version actually running
SERIALNO	The software serial number
UPTIME	The server uptime
MEMORY	The memory usage of the backend
SESSIONS	The number of open sessions
WEBSOCKS	The number of open (message) websocket connections

Parameters: none

Return Codes:

Code	Description
200	OK, the Dictionary with the status information is returned as payload.

8.2.24 /api/v1/dbstate

This API call delivers some status information about the backend's connection to the database server. It may be used by a frontend to evaluate if the backend actually is connected to the (read-only) backeup database and therefore no changes to the database content are allowed

Supported HTTP methods: GET,HEAD,OPTIONS

GET /api/v1/dbstate

Returns a SatDbState document listing some status information about the database connection.

Parameters: none

Return Codes:

Code	Description
200	OK, the SatDbState document with the status information is returned as payload.

8.2.25 /api/v1/dbversion

This API call delivers the version information about the database connected to the backend.

Supported HTTP methods: GET,HEAD,OPTIONS

GET /api/v1/dbversion

Returns a SatDbVersion document showing the actual version of the database and the version required by the backend.

Parameters: none

Return Codes:

Code	Description
200	OK, the SatDbState document with the status information is returned as payload.

8.2.26 /api/v1/satellites

This API endpoint gives access to various functions of the sat-nms satellite database, permitting to read, add, change or delete entries at the database

Supported HTTP methods: GET, POST, PATCH, DELETE, HEAD, OPTIONS**GET /api/v1/satellites**

Returns the list of stored satellites as an array ofSatDbSatellite data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of stored satellites as an array ofSatDbSatellite data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document with all satellites and their attributes.
401	not logged in. In this case anApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}

Returns the basic properties of the satellite addressed by {satelliteId} as aSatDbSatellite data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The requested SatDbSatellite data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites

Creates a new satellite with the given attributes . The unique *satelliteId* is generated by the database backend and returned in the response document.

Parameters: none

Expected Payload: The SatDbSatellite data object to store. Any *satelliteId* definition in the source is ignored as this will be set by the database when the new entry is created. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbSatellite data object added to the database. The replied data object contains the *satelliteId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbSatellite data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}

Updates an existing satellite with the given *satelliteId* from the attached SatDbSatellite data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbSatellite data object containing the fields to be updated in the database. If the data object contains a *satelliteId* key, the value is ignored. The database record is solely identified by *satelliteId* set in the URL, the *satelliteId* of the record is immutable. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbSatellite data object read from the database after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}

Remove a satellite from the database. This deletes the satellite's record from the satellite table and all records from other tables like beacons, TLEs etc which unambiguously depend on the deleted satellite.

Parameters:

Parameter	Description
satelliteId	Id of the satellite to delete

Expected Payload: none

Replied Payload: The SatDbSatellite data object which has been deleted.

Return Codes:

Code	Description
200	OK, the satellite has been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}/positions

Returns the list of satellite positions for a given satellite as an array of SatDbPosition data objects.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of satellite positions as an array of SatDbPosition data objects. This array may be empty if there are no positions defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/beacons

Returns the list of satellite beacons for a given satellite as an array of SatDbBeacon data objects.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of satellite beacons as an array ofSatDbBeacon data objects. This array may be empty if there are no beacons defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/beacons/{beaconId}

Returns the information stored for a particular satellite beacon addressed by {satelliteId} / {beaconId} as a SatDbBeacon data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
beaconId	Id of the beacon.

Expected Payload: none

Replied Payload: The requested SatDbBeacon data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case anApiError document is returned, describing details of the error.

Code	Description
404	no satellite satellite beacon exists with the given *satelliteId* / *beaconId*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites/{satelliteId}/beacons

Creates a new satellite beacon with the given attributes. {satelliteId} specifies the satellite for which the beacon shall be created. The unique *beaconId* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbBeacon data object to store. Any *beaconId* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *satellite_Id*, the newly created SatDbBeacon data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbBeacon data object added to the datbase. The replied data object contains the *beaconId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbBeacon data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}/beacons/{beaconId}

Updates an existing satellite beacon with the given *satelliteId* / *beaconId* from the attached SatDbBeacon data object.

Parameters:

Parameter	Description

Parameter	Description
satelliteId	Id of the satellite.
beaconId	Id of the beacon.

Expected Payload: The SatDbBeacon data object containing the fields to be updated in the database. If the data object contains values for *beaconId* and / or *satelliteId*, these values are ignored. *beaconId* and *satelliteId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbBeacon data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite satellite beacon exists with the given *satelliteId* / *beaconId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/beacons/{beaconId}

Remove a satellite beacon from the database.

Parameters:

Parameter	Description
satelliteId	Id of the satellite the beacon belongs to.
beaconId	Id of the beacon to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the beacon has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite satellite beacon exists with the given *satelliteId* / *beaconId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/beacons

Remove all satellite beacons which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all beacons for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}/tcchans

Returns the list of satellite TC channels for a given satellite as an array of SatDbTc data objects.

Parameters:

Parameter	Description

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of satellite TC channels as an array ofSatDbTc data objects. This array may be empty if there are no TC channels defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/tcchans/{tcId}

Returns the information stored for a particular satellite TC channel addressed by {satelliteId} / {tcId} as a SatDbTc data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
tcId	Id of the TC channel.

Expected Payload: none

Replied Payload: The requested SatDbTc data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite channel.
401	not logged in. In this case anApiError document is returned, describing details of the error.

Code	Description
404	no satellite TC channel exists with the given *satelliteId* / *tcId*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites/{satelliteId}/tcchans

Creates a new satellite TC channel with the given attributes. {satelliteId} specifies the satellite for which the TC channel shall be created. The unique *tcId* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbTc data object to store. Any *tcId* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *satelliteId*, the newly created SatDbTc data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbTc data object added to the datbase. The replied data object contains the *tcId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbTc data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}/tcchans/{tcId}

Updates an existing satellite TC channel with the given *satelliteId* / *tcId* from the attached SatDbTc data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Parameter	Description
tcId	Id of the TC channel.

Expected Payload: The SatDbTc data object containing the fields to be updated in the database. If the data object contains values for *tcId* and / or *satelliteId*, these values are ignored. *tcId* and *satelliteId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbTc data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite satellite TC channel exists with the given *satelliteId* / *tcId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tcchans/{tcId}

Remove a satellite TC channel from the database.

Parameters:

Parameter	Description
satelliteId	Id of the satellite the TC channel belongs to.
tcId	Id of the TC channel to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description

Code	Description
204	NO CONTENT, the TC channel has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite satellite TC channel exists with the given *satelliteId* / *tcId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tcchans

Remove all satellite TC channels which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all TC channels for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}/tmchans

Returns the list of satellite TM channels for a given satellite as an array of SatDbTm data objects.

Parameters:

Parameter	Description

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of satellite TM channels as an array ofSatDbTm data objects. This array may be empty if there are no tm channels defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/tmchans/{tmId}

Returns the information stored for a particular satellite TM channel addressed by {satelliteId} / {tmId} as a SatDbTm data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
tmId	Id of the TM channel.

Expected Payload: none

Replied Payload: The requested SatDbTm data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite channel.
401	not logged in. In this case anApiError document is returned, describing details of the error.

Code	Description
404	no satellite TM channel exists with the given *satelliteId* / *tmId*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites/{satelliteId}/tmchans

Creates a new satellite TM channel with the given attributes. {satelliteId} specifies the satellite for which the tm channel shall be created. The unique *tmId* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbTm data object to store. Any *tmId* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *satelliteId*, the newly created SatDbTm data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbTm data object added to the datbase. The replied data object contains the *tmId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbTm data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}/tmchans/{tmId}

Updates an existing satellite TM channel with the given *satelliteId* / *tmId* from the attached SatDbTm data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Parameter	Description
tmId	Id of the TM channel.

Expected Payload: The SatDbTm data object containing the fields to be updated in the database. If the data object contains values for *tmId* and / or *satelliteId*, these values are ignored. *tmId* and *satelliteId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbTm data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite satellite TM channel exists with the given *satelliteId* / *tmId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tmchans/{tmId}

Remove a satellite TM channel from the database.

Parameters:

Parameter	Description
satelliteId	Id of the satellite the TM channel belongs to.
tmId	Id of the TM channel to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description

Code	Description
204	NO CONTENT, the TM channel has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite satellite TM channel exists with the given *satelliteId* / *tmId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tmchans

Remove all satellite TM channels which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all TM channels for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}/i11params

Returns the list of I11 parameter sets for a given satellite as an array of SatDbI11Data data objects.

Parameters:

Parameter	Description

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of I11 parameter sets as an array ofSatDbI11Data data objects. This array may be empty if there are no I11 parameter sets defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/i11params/{i11Id}

Returns the information stored for a particular I11 parameter set addressed by {satelliteId} / {i11Id} as a SatDbI11Data data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
i11Id	Id of the I11 parameter set.

Expected Payload: none

Replied Payload: The requested SatDbI11Data data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case anApiError document is returned, describing details of the error.

Code	Description
404	no satellite I11 parameter set exists with the given *satelliteId* / *i11Id*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites/{satelliteId}/i11params

Creates a new I11 parameter set with the given attributes. {satelliteId} specifies the satellite for which the I11 parameter set shall be created. The unique *i11Id* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbI11Data data object to store. Any *i11Id* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *satellite_Id*, the newly created SatDbI11Data data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbI11Data data object added to the datbase. The replied data object contains the *i11Id* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbI11Data data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}/i11params/{i11Id}

Updates an existing I11 parameter set with the given *satelliteId* / *i11Id* from the attached SatDbI11Data data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Parameter	Description
i11Id	Id of the I11 parameter set.

Expected Payload: The SatDbI11Data data object containing the fields to be updated in the database. If the data object contains values for *i11Id* and / or *satelliteId*, these values are ignored. *i11Id* and *satelliteId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbI11Data data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite I11 parameter set exists with the given *satelliteId* / *i11Id*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/i11params/{i11Id}

Remove a I11 parameter set from the database.

Parameters:

Parameter	Description
satelliteId	Id of the satellite the I11 parameter set belongs to.
i11Id	Id of the I11 parameter set to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description

Code	Description
204	NO CONTENT, the I11 parameter set has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite I11 parameter set exists with the given *satelliteId* / *i11Id*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/i11params

Remove all I11 parameter sets which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all I11 parameter sets for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satellites/{satelliteId}/tleparams

Returns the list of TLE parameter sets for a given satellite as an array of SatDbTLEData data objects.

Parameters:

Parameter	Description

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of TLE parameter sets as an array ofSatDbTLEData data objects. This array may be empty if there are no TLE parameter sets defined for this satellite. As there may be actually only one TLE parameter set for each satellite, the array may contain only zero or one elements.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/satellites/{satelliteId}/tleparams/{noradNumber}

Returns the information stored for a particular TLE parameter set addressed by {satelliteId} / {noradNumber} as a SatDbTLEData data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
noradNumber	Id / norad number of the TLE parameter set.

Expected Payload: none

Replied Payload: The requested SatDbTLEData data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.

Code	Description
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite TLE parameter set exists with the given *satelliteId* / *noradNumber*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satellites/{satelliteId}/tleparams

Creates a new TLE parameter set with the given attributes. {satelliteId} specifies the satellite for which the TLE parameter set shall be created. The unique *noradNumber* is taken from the *noradNumber* field in the satellite's master data and returned in the response document. Hence it is important that the *noradNumber* field in the satellite's master data has been set before to the correct value.

As there may be only TLE parameter set assigned to a satellite, this POST method behaves in a special way: If there already exists a TLE parameter set for this satellite, it will be silently overwritten by the POST call. The call proceeds, stores the new data and returns a 201 return code. This behavior ensures, that not more than one TLE parameter set can be assigned to a satellite.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: The SatDbTLEData data object to store. Any *noradNumber* definition in the source is ignored as this will be taken from the *noradNumber* field in the satellite's master data when the new entry is created. The same applies to *satellite_Id*, the newly created SatDbTLEData data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbTLEData data object added to the datbase. The replied data object contains the *noradNumber* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbTLEData data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satellites/{satelliteId}/tleparams/{noradNumber}

Updates an existing TLE parameter set with the given *satelliteId* / *noradNumber* from the attached SatDbTLEData data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.
noradNumber	Id of the TLE parameter set.

Expected Payload: The SatDbTLEData data object containing the fields to be updated in the database. If the data object contains values for *noradNumber* and / or *satelliteId*, these values are ignored. *noradNumber* and *satelliteId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbTLEData data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite TLE parameter set exists with the given *satelliteId* / *noradNumber*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tleparams/{noradNumber}

Remove a TLE parameter set from the database.

Parameters:

Parameter	Description
satelliteId	Id of the satellite the TLE parameter set belongs to.
noradNumber	Id of the TLE parameter set to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the TLE parameter set has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite TLE parameter set exists with the given *satelliteId* / *noradNumber*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/tleparams

Remove all TLE parameter sets which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all TLE parameter sets for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satellites/{satelliteId}/ttracks

In general, the table track ('ttrack') API calls are located at /api/v1/antennas. The only call located at /api/v1/satellites is to temove all table track data sets which belong to the given *satelliteId* (for all antennas).

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all table track data sets for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

8.2.27 /api/v1/satoperators

This API endpoint gives access to various functions of the sat-nms satoperator database table, permitting to read, add, change or delete entries at the database

Supported HTTP methods: GET, POST, PATCH, DELETE, HEAD, OPTIONS

The API generally does not permit PATCH or DELETE operations on entire tables, this to protect the database from being accidentally be deleted. Even POST operations only work with single data objects.

GET /api/v1/satoperators

Returns the list of stored satoperators as an array of SatDbSatOperator data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of stored satoperators as an array of SatDbSatOperator data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document with all satoperators and their attributes.

Code	Description
401	not logged in. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/satoperators/{operatorId}

Returns the basic properties of the satoperator addressed by {operatorId} as a SatDbSatOperator data object.

Parameters:

Parameter	Description
operatorId	Id of the satoperator.

Expected Payload: none

Replied Payload: The requested SatDbSatOperator data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satoperator.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satoperator with the given *operatorId* does not exists. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/satoperators

Creates a new satoperator with the given attributes. The unique *operatorId* is generated by the database backend and returned in the response document.

Parameters: none

Expected Payload: The SatDbSatOperator data object to store. Any *operatorId* definition in the source is ignored as this will be set by the database when the new entry is created. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbSatOperator data object added to the datbase. The replied data object contains the *operatorId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbSatOperator data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/satoperators/{operatorId}

Updates an existing satellite operator with the given *operatorId* from the attached SatDbSatOperator data object.

Parameters:

Parameter	Description
operatorId	Id of the satoperator.

Expected Payload: The SatDbSatOperator data object containing the fields to be updated in the database. If the data object contains an *operatorId* key, the value is ignored. The database record is solely identified by *operatorId* set in the URL, the *operatorId* of the record is immutable. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbSatOperator data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	the satellite operator with the given *operatorId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/satoperators/{operatorId}

Remove a satoperator from the database. This deletes the satoperator's record from the satoperator table and removes all references to the deleted satoperator in the *satellites* table.

Parameters:

Parameter	Description
operatorId	Id of the satoperator to delete

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the satellite has been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	the satellite operator with the given *operatorId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

8.2.28 /api/v1/channels

This API endpoint gives access to various functions of the*channels* database table, permitting to read, add, change or delete entries at the database. This database table holds all satellite channels known in the satnms database.

Supported HTTP methods: GET, POST, PATCH, DELETE, HEAD, OPTIONS

The API generally does not permit PATCH or DELETE operations on entire tables, this to protect the database from being accidentally be deleted. Even POST operations only work with single data objects.

GET /api/v1/channels/

Returns the list of all satellite channel records as an array ofChannelData data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of satellite channel records as an array ofChannelData data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/channels/ip

Returns the list of all 'IP' type satellite channel records as an array of ChannelData data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of satellite channel records as an array of ChannelData data objects. This array may be empty if there are no such channel records in the database..

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/channels/asi

Returns the list of all 'ASI' type satellite channel records as an array of ChannelData data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of satellite channel records as an array of ChannelData data objects. This array may be empty if there are no such channel records in the database.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/channels/sat

Returns the list of all 'SAT' type satellite channel records as an array ofChannelData data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of satellite channel records as an array ofChannelData data objects. This array may be empty if there are no such channel records in the database.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/channels/sat/{satelliteId}

Returns the list of 'SAT' type satellite channel records for a given satellite as an array of ChannelData data objects.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of satellite channel records as an array ofChannelData data objects. This array may be empty if there are no channel records defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/channels/{channelId}

Returns the information stored for a particular channel record addressed by {channelId} as a ChannelData data object.

Parameters:

Parameter	Description
channelId	Id of the channel record.

Expected Payload: none

Replied Payload: The requested ChannelData data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite channel record exists with the given *channelId*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/channels

Creates a new channel record with the given attributes.

Parameters: none

Expected Payload: The ChannelData data object to store. The channel definition must conform the following conditions:

- The *decoderInput* field must be set to one of 'SAT', 'IP' or 'ASI' to define the type of channel.
- The *name* field must be set to a value which is unique for the given satellite or the API call will decline to create the database record.
- 'SAT' type records must contain a valid *satelliteId*
- Any *channelId* definition in the source is ignored as this will be set by the database when the new entry is created.

Replied Payload: The ChannelData data object added to the datbase. The replied data object contains the *channelId* assigned to the newly created record.

Return Codes:

Code	Description

Code	Description
201	CREATED, the created ChannelData data object is replied as payload
400	BAD_REQUEST if the supplied ChannelData does not conform the conditions listed above.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/channels/{channelId}

Updates an existing channel record with the given *channelId* from the attached ChannelData data object.

Parameters:

Parameter	Description
channelId	Id of the channel record.

Expected Payload: The ChannelData data object containing the fields to be updated in the database. Fields not contained in the supplied data object are retained unchanged. The channel definition must conform the following conditions:

- If it changes the *name* of the record, this must be set to a value which is unique for the given satellite or the API call will decline to create the database record.
- 'SAT' type records must contain a valid *satelliteId*
- Any *channelId* definition in the source is ignored as the *channelId* is immutable once a record has been created.

Replied Payload: The ChannelData data object read from the database after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
400	BAD_REQUEST if the supplied ChannelData does not conform the conditions listed above.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	no satellite channel record exists with the given *channelId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/channels/{channelId}

Remove a channel record from the database.

Parameters:

Parameter	Description
channelId	Id of the channel record to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the channel record has been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite channel record exists with the given *channelId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/channels/sat/{satelliteId}

Remove all channel records which belong to the given *satelliteId*.

Parameters:

Parameter	Description
satelliteId	Id of the satellite

Return Codes:

Code	Description
204	NO CONTENT, all channel records for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

8.2.29 /api/v1/streamkeys

This API endpoint gives access to various functions of the *streamkeys* database table, permitting to read, add, change or delete entries at the database. This database table holds all BISS-1/BISS-E keys and SRT passphrases known in the sat-nms database.

Supported HTTP methods: GET, POST, PATCH, DELETE, HEAD, OPTIONS

The API generally does not permit PATCH or DELETE operations on entire tables, this to protect the database from being accidentally be deleted. Even POST operations only work with single data objects.

GET /api/v1/streamkeys

Returns the list of stored stream keys as an array of StreamKeyData data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of stored stream keys as an array of StreamKeyData data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document with all streamkeys and their attributes.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/streamkeys/{keyId}

Returns the basic properties of the stream key addressed by {keyId} as aStreamKeyData data object.

Parameters:

Parameter	Description
keyId	Id of the stream key.

Expected Payload: none

Replied Payload: The requested StreamKeyData data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested stream key.
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	stream key with the given *keyId* does not exists. In this case anApiError document is returned, describing details of the error.

POST /api/v1/streamkeys

Creates a new stream key with the given attributes. The unique*keyId* is generated by the database backend and returned in the response document.

Parameters: none

Expected Payload: The StreamKeyData data object to store. Any *keyId* definition in the source is ignored as this will be set by the database when the new entry is created. The *name* field in the supplied payload must be unique over the entire table or the API call will decline to create the database record.

Replied Payload: The StreamKeyData data object added to the database. The replied data object contains the *keyId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created StreamKeyData data object is replied as payload
400	BAD_REQUEST. Either the *name* supplied with the request is not unique or the*key* does not conform to the format restrictions for the given *keyType*

Code	Description
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/streamkeys/{keyId}

Updates an existing stream key with the given *keyId* from the attached StreamKeyData data object.

Parameters:

Parameter	Description
keyId	Id of the stream key.

Expected Payload: The StreamKeyData data object containing the fields to be updated in the database. If the data object contains an *keyId* key, the value is ignored. The database record is solely identified by *keyId* set in the URL, the *keyId* of the record is immutable. Keys not contained in the supplied data object are retained unchanged. The *name* field in the supplied payload must be unique over the entire table or the API call will decline to modify the database record.

Replied Payload: The StreamKeyData data object read from the database after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
400	BAD_REQUEST. Either the *name* supplied with the request is not unique or the*key* does not conform to the format restrictions for the given *keyType*
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	the stream key with the given *keyId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/streamkeys/{keyId}

Remove a stream key from the database.

Parameters:

Parameter	Description
keyId	Id of the stream key to delete

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the satellite has been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	the stream key with the given *keyId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

8.2.30 /api/v1/antennas

This API endpoint gives access to various functions of the sat-nms antenna database table, permitting to read, add, change or delete entries at the database

Supported HTTP methods: GET, POST, PATCH, DELETE, HEAD, OPTIONS

The API generally does not permit PATCH or DELETE operations on entire tables, this to protect the database from being accidentally be deleted. Even POST operations only work with single data objects.

GET /api/v1/antennas

Returns the list of stored antennas as an array of SatDbAntenna data objects.

Parameters: none

Expected Payload: none

Replied Payload: The list of stored antennas as an array of SatDbAntenna data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document with all antennas and their attributes.
401	not logged in. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}

Returns the basic properties of the antenna addressed by {antennaId} as a SatDbAntenna data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.

Expected Payload: none

Replied Payload: The requested SatDbAntenna data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested antenna.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	antenna with the given *antennaId* does not exists. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/antennas

Creates a new antenna with the given attributes. The unique *antennaId* is generated by the database backend and returned in the response document.

Parameters: none

Expected Payload: The SatDbAntenna data object to store. Any *antennaId* definition in the source is ignored as this will be set by the database when the new entry is created. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbAntenna data object added to the database. The replied data object contains the *antennaId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbAntenna data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}

Updates an existing antenna with the given *antennaId* from the attached SatDbAntenna data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.

Expected Payload: The SatDbAntenna data object containing the fields to be updated in the database. If the data object contains an *antennaId* key, the value is ignored. The database record is solely identified by *antennaId* set in the URL, the *antennaId* of the record is immutable. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbAntenna data object read from the database after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	antenna with the given *antennaId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}

Remove a antenna from the database. This deletes the antenna's record from the antenna table and all records from the *satpositions* table which refer to the deleted antenna.

Parameters:

Parameter	Description
antennaId	Id of the antenna to delete

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the satellite has been deleted.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	antenna with the given *antennaId* does not exists. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}/positions

Returns the list of satellite positions for a given antenna as an array of SatDbPosition data objects.

Parameters:

Parameter	Description
antennaId	Id of the antenna.

Expected Payload: none

Replied Payload: The list of satellite positions as an array of SatDbPosition data objects. This array may be empty if there are no satellite positions defined for this antenna.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information

Code	Description
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	the antenna with the given *antennaId* does not exists. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/antennas/{antennaId}/positions/{positionId}

Returns the information stored for a particular satellite position addressed by {antennaId} / {positionId} as a SatDbPosition data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
positionId	Id of the satellite position.

Expected Payload: none

Replied Payload: The requested SatDbPosition data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested antenna.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no antenna satellite position exists with the given *antennaId* / *positionId*. In this case an ApiError document is returned, describing details of the error.

ST /api/v1/antennas/{antennaId}/positions

Creates a new satellite position with the given attributes. {antennaId} specifies the antenna for which the satellite position shall be created. The unique *positionId* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description

Parameter	Description
antennaId	Id of the antenna.

Expected Payload: The SatDbPosition data object to store. Any *positionId* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *antennaId*, the newly created SatDbPosition data object will be linked to the antenna specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbPosition data object added to the database. The replied data object contains the *positionId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbPosition data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}/positions/{positionId}

Updates an existing satellite position with the given *antennaId* / *positionId* from the attached SatDbPosition data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
positionId	Id of the satellite position.

Expected Payload: The SatDbPosition data object containing the fields to be updated in the database. If the data object contains values for *positionId* and / or *antennaId*, these values are ignored. *positionId* and *antennaId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbPosition data object read from the database after the requested changes have been applied.

Return Codes:

Code	Description

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no antenna satellite position exists with the given *antennaId* / *positionId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/positions/{positionId}

Remove a satellite position from the database.

Parameters:

Parameter	Description
antennaId	Id of the antenna the satellite position belongs to.
positionId	Id of the satellite position to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the satellite position has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no antenna satellite position exists with the given *antennaId* / *positionId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/positions

Remove all satellite positions which belong to the given *antennaId*.

Parameters:

Parameter	Description
antennaId	Id of the antenna

Return Codes:

Code	Description
204	NO CONTENT, all satellite positions for the selected antenna have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	antenna with the given *antennaId* does not exist. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}/ttracks

Returns the list of table track data sets for a given antenna as an array of SatDbTableTracking data objects.

Parameters:

Parameter	Description
antennaId	Id of the antenna.

Expected Payload: none

Replied Payload: The list of table track data sets as an array of SatDbTableTracking data objects. This array may be empty if there are no table track data sets defined for this antenna.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	antenna with the given *antennaId* does not exists. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/antennas/{antennaId}/{satelliteId}/ttracks

Returns the list of table track data sets for a given satellite/antenna combination as an array of SatDbTableTracking data objects.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The list of table track data sets as an array ofSatDbTableTracking data objects. This array may be empty if there are no table track data sets defined for this satellite.

Return Codes:

Code	Description
200	OK, returns a JSON document with the requested information
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

GET /api/v1/antennas/{antennaId}/{satelliteId}/ttracks/{ttId}

Returns the information stored for a particular table track data set addressed by {antennaId} / {satelliteId} / {ttId} as a SatDbTableTracking data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
satelliteId	Id of the satellite.
ttId	Id of the table track data set.

Expected Payload: none

Replied Payload: The requested SatDbTableTracking data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite table track data set exists with the given *satelliteId* / *ttId*. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/antennas/{antennaId}/{satelliteId}/ttracks

Creates a new table track data set with the given attributes. {antennaId} / {satelliteId} specifies the satellite / antenna combination for which the table track data set shall be created. The unique *ttId* is generated by the database backend and returned in the response document.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
satelliteId	Id of the satellite.

Expected Payload: The SatDbTableTracking data object to store. Any *ttId* definition in the source is ignored as this will be set by the database when the new entry is created. The same applies to *satellite_Id*, the newly created SatDbTableTracking data object will be linked to the satellite specified in the URL. If other keys of the data object are missing, default values will be assigned these keys.

Replied Payload: The SatDbTableTracking data object added to the datbase. The replied data object contains the *ttId* assigned to the newly created record.

Return Codes:

Code	Description
201	CREATED, the created SatDbTableTracking data object is replied as payload
401	not logged in. In this case an ApiError document is returned,describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}/{satelliteId}/ttracks/{ttId}

Updates an existing table tracking data set with the given *antennaId* / *satelliteId* / *ttId* from the attached SatDbTableTracking data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
satelliteId	Id of the satellite.
ttId	Id of the table track data set.

Expected Payload: The SatDbTableTracking data object containing the fields to be updated in the database. If the data object contains values for any of *ttId*, *satelliteId* or *antennaId*, these values are ignored. *ttId*, *satelliteId* and *antennaId* are immutable once a record has been created. Keys not contained in the supplied data object are retained unchanged.

Replied Payload: The SatDbTableTracking data object read from the datbase after the requested changes have been applied.

Return Codes:

Code	Description
200	OK, changes have been applied.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no satellite table track data set exists with the given *satelliteId* / *ttId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/{satelliteId}/ttracks/{ttId}

Remove a table track data set from the database.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
satelliteId	Id of the satellite the table track data set belongs to.

Parameter	Description
ttId	Id of the table track data set to delete.

Expected Payload: none

Replied Payload: none

Return Codes:

Code	Description
204	NO CONTENT, the table track data set has been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	no satellite table track data set exists with the given *satelliteId* / *ttId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/{satelliteId}/ttracks

Remove all table track data sets which belong to the given *satelliteId* / *antennaId* combination.

Parameters:

Parameter	Description
satelliteId	Id of the satellite
antennaId	Id of the antenna.

Return Codes:

Code	Description
204	NO CONTENT, all table track data sets for the selected satellite have been deleted.
401	not logged in. In this case an ApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case an ApiError document is returned, describing details of the error.

Code	Description
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/ttracks

Remove all table track data sets which belong to the given antenna.

Parameters:

Parameter	Description
antennaId	Id of the antenna

Return Codes:

Code	Description
204	NO CONTENT, all table track data sets for the selected satellite have been deleted.
401	not logged in. In this case anApiError document is returned,describing details of the error.
404	satellite with the given *satelliteId* does not exist. In this case anApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}/beacon-atten/{beaconId}

Returns the attenuation value addressed by {antennaId} / {beaconId} as a SatDbBeaconAttenuation data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
beaconId	Id of the beacon.

Expected Payload: none

Replied Payload: The requested SatDbBeaconAttenuation data object. If no attenuation has

been stored for this antennaId/beaconId combination, an empty SatDbBeaconAttenuation data object with the attenuation value set to 0.0 is returned.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or beaconId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/antennas/{antennaId}/beacon-atten/{beaconId}

Sets the attenuation value for an {antennaId} / {beaconId} combination. Returns the attenuation set as a SatDbBeaconAttenuation data object. If no attenuation record exists for this antenna / beacon combination a new one is created. If there is already an attenuation record for this combination, the existing one will be overwritten.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
beaconId	Id of the beacon.

Expected Payload: The attenuation to set as a SatDbBeaconAttenuation data object. Only the attenuation is read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbBeaconAttenuation data object with the updated attenuation .

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or beaconId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}/beacon-atten/{beaconId}

Sets the attenuation value for an {antennaId} / {beaconId} combination. Returns the attenuation set as a SatDbBeaconAttenuation data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
beaconId	Id of the beacon.

Expected Payload: The attenuation to set as a SatDbBeaconAttenuation data object. Only the attenuation is read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbBeaconAttenuation data object with the updated attenuation .

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or beaconId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *beaconId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/beacon-atten/{beaconId}

Deletes the attenuation value addressed by {antennaId} / {beaconId}.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
beaconId	Id of the beacon.

Expected Payload: none

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the record has been deleted
400	BAD_REQUEST, antennaId or beaconId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *beaconId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}/tc-atten/{tcId}

Returns the attenuation values addressed by {antennaId} / {tcId} as a SatDbTcAttenuation data object. If no attenuation has been stored for this antennaId/tcId combination, an empty SatDbTcAttenuation data object with the attenuation values set to 0.0 is returned.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tcId	Id of the tc channel.

Expected Payload: none

Replied Payload: The requested SatDbTcAttenuation data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tcId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/antennas/{antennaId}/tc-atten/{tcId}

Sets the attenuation values for an {antennaId} / {tcId} combination. Returns the attenuation set as a SatDbTcAttenuation data object. If no attenuation record exists for this antenna / tc combination a new one is created. If there is already an attenuation record for this combination, the existing one will be overwritten.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tcId	Id of the tc channel.

Expected Payload: The attenuation to set as a SatDbTcAttenuation data object. Only the attenuation values are read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbTcAttenuation data object with the updated attenuation .

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tcId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}/tc-atten/{tcId}

Modifies the attenuation values for an {antennaId} / {tcId} combination. Returns the attenuation set as a SatDbTcAttenuation data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tcId	Id of the tc channel.

Expected Payload: One or both attenuation values to set in aSatDbTcAttenuation data object. Only the attenuation values are read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbTcAttenuation data object with the updated attenuation.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tcId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case anApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *tcId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/tc-atten/{tcId}

Deletes the attenuation values addressed by {antennaId} / {tcId}.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tcId	Id of the tc channel.

Expected Payload: none

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the record has been deleted
400	BAD_REQUEST, antennaId or tcId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *tcId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/antennas/{antennaId}/tm-atten/{tmId}

Returns the attenuation values addressed by {antennaId} / {tmId} as a SatDbTmAttenuation data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tmId	Id of the tm channel.

Expected Payload: none

Replied Payload: The requested SatDbTmAttenuation data object. If no attenuation has been stored for this antennaId/tcId combination, an empty SatDbTmAttenuation data object with the attenuation values set to 0.0 is returned.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tmId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.

Code	Description
401	not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/antennas/{antennaId}/tm-atten/{tmId}

Sets the attenuation values for an {antennaId} / {tmId} combination. Returns the attenuation values set as a SatDbTmAttenuation data object. If no attenuation record exists for this antenna / tm combination a new one is created. If there is already an attenuation record for this combination, the existing one will be overwritten.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tmId	Id of the tm channel.

Expected Payload: The attenuation to set as a SatDbTmAttenuation data object. Only the attenuation values are read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbTmAttenuation data object with the updated attenuation .

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tmId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/antennas/{antennaId}/tm-atten/{tmId}

Modifies the attenuation values for an {antennaId} / {tmId} combination. Returns the attenuation set as a SatDbTmAttenuation data object.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tmId	Id of the tm channel.

Expected Payload: One or both attenuation values to set in aSatDbTmAttenuation data object. Only the attenuation values are read from this data object, any IDs passed to this API function are ignored. The IDs are defined solely by the URL parameters.

Replied Payload: The SatDbTmAttenuation data object with the updated attenuation.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
400	BAD_REQUEST, antennaId or tmId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *tmId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/antennas/{antennaId}/tm-atten/{tmId}

Deletes the attenuation values addressed by {antennaId} / {tmId}.

Parameters:

Parameter	Description
antennaId	Id of the antenna.
tmId	Id of the tm channel.

Expected Payload: none

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the record has been deleted
400	BAD_REQUEST, antennaId or tmId could not be parsed to a numeric identifier. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.
404	no attenuation record exists with the given *satelliteId* / *tmId*. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

8.2.31 /api/v1/satdetails

This API endpoint reports all relevant data for a satellite in a compact form. It has been added for convenience, unburdening the front end programmer from the need to gather this information from different database tables using multiple API calls.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/satdetails/{satelliteId}

Returns detailed properties of the satellite addressed by {satelliteId} as a SatDbSatDetails data object.

Parameters:

Parameter	Description
satelliteId	Id of the satellite.

Expected Payload: none

Replied Payload: The requested SatDbSatDetails data object.

Return Codes:

Code	Description
200	OK, returns a document describing the requested satellite.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	satellite with the given *satelliteId* does not exists. In this case anApiError document is returned, describing details of the error.

8.2.32 /api/v1/tleimport

This API endpoint lets you upload and import a list of TLE parameter sets from a data file. The expected file format is compatible to the well known 'geo.txt' file from celestrak.com. The file must contain three lines of text for each satellite, the firs line contains the satellite name, followed by two lines in TLE format. The norad number contained in both lines of the TLE format is used to identify for which satellite each record shall be used. The satellite name is treated as a comment only.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/tleimport

Expects a SatDbTleImport document containing the file to import along with some additional parameters.

Parameters: none

Expected Payload: The SatDbTleImport document containing the file to import and the import mode to use.

Replied Payload: none, except for errors.

Return Codes:

Code	Description
204	OK, the file has been imported to the database. Do data is returned.
400	The file could not be parsed. In this case anApiError document is returned, describing details of the error.
401	not logged in. In this case anApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

8.2.33 /api/v1/eventreport

This API endpoint lets you create reports from the M&C system event database. The M&C systems managed by the backend share a common event database which store all faults, warnings and informational messages occurring in the particular M&C systems.

A report from the event database is created by sending anEventReportRequest document with

a POST call to this API endpoint. The EventReportRequest defines the time span to read and some filter settings which allow to read a set of messages with a specific content.

The API call responds with a EventReport document containing the requested event report.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/eventreport

Expects an EventReportRequest document containing the time span to read and the report filter settings.

Parameters: none

Expected Payload: The EventReportRequest document containing the time span to read and the report filter settings.

Replied Payload: The EventReport document containing the requested report.

Return Codes:

Code	Description
200	OK, the request has been processed, the report generated is replied.
500	The event database does not reply (internal error). In this case anApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.34 /api/v1/eventack

The sat-nms event database provides a "not yet acknowledged" flag with each event in the database. This flag is initially set for all faults. This API endpoint gives access to the "acknowledge" function which clears this flag for a single event or for all events which have the flag set.

To acknowledge on or all events, the front end has to send anEventAck document with a POST call to this API end point. The EventAck document defines if all events or a particular one shall be acknowledged.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/eventack

Expects an EventAck document which defines if all events or a particular one shall be acknowledged.

Parameters: none

Expected Payload: The EventAck document which defines if all events or a particular one shall be acknowledged.

Replied Payload: none, except for errors.

Return Codes:

Code	Description
204	OK, the request has been processed. Do data is returned. There is no error checking, acknowledging a non-existing event or an event which does not require acknowledging is not treated as a fault.
500	The event database does not reply (internal error). In this case anApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.35 /api/v1/trackmem

When subscribing for a '.state.mode4' parameter of a SatService ACU-ODM, the front end receives a message which indicates 'a new tracking history for this antenna is available' instead of sending the bulky tracking history itself over the websocket connection.

After the front end received this message, it can use the /api/v1/trackmem API call to retrieve the full tracking history as a TrackingHistory data object.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/trackmem/{odmName}

Parameters:

Parameter	Description
odmName	The device name of the ODM for which the tracking history shall be read. This must be a fully qualified name including name of the M&C where the ODM is managed.

Expected Payload: none

Replied Payload: A TrackingHistory document containing the tracking history of the referenced antenna controller.

Return Codes:

Code	Description

Code	Description
200	OK, the requested TrackingHistory document is returned.
400	Either the requested device does not exist or the device has not yet sent a tracking history. This may happen if the front end did no subscribe for the 'state.mode4' of the ODM before or if the ODM is not operational. In this case an ApiError document is returned, describing details of the error.
401	not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.36 /api/v1/treeview

This API end point lets you retrieve the treeview data structure as a whole or partially by requesting only a branch of the tree. The API also provides a PUT method for this end point which lets you replace the user defined part of the tree for a given M&C name.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/treeview

Gets the complete tree definition for all M&C systems configured in the backend. Includes the auto-generated and the user defined parts of the tree definition

Parameters: none

Expected Payload: none

Replied Payload: A TreeViewNode document containing the complete tree view tree, starting with the ROOT node of the tree.

Return Codes:

Code	Description
200	OK, the requested TreeViewNode document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/treeview/{mncName}

Gets the tree definition for a given M&C system. Includes the user defined part of the tree definition as well as the device list for this M&C system.

Parameters:

Parameter	Description

Parameter	Description
mncName	The name of the M&C for which the tree definition shall be read.

Expected Payload: none

Replied Payload: A TreeViewNode document containing the tree branch for the given M&C, starting with the MNCNODE node for this M&C.

Return Codes:

Code	Description
200	OK, the requested TreeViewNode document is returned.
404	The requested M&C system does not exist or is actually offline. In this case an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/treeview/{mncName}/{subsystemName}

Gets the tree definition for a given M&C subsystem.

Parameters:

Parameter	Description
mncName	The name of the M&C for which the tree definition shall be read.
subsystemName	The name of the subsystem to retrieve. This subsystem name also may address nested subsystems, e.g. `SUBSYS-1.SUB_SYS-2` denotes a subsystem `SUSBSYS-2` contained in `SUBSYS-1`

Expected Payload: none

Replied Payload: A TreeViewNode document containing the tree branch for the given M&C subsystem, starting with the SUBSYSTEM node for this M&C subsystem.

Return Codes:

Code	Description
200	OK, the requested TreeViewNode document is returned.

Code	Description
404	Either the requested M&C system does not exist or is actually offline or no subsystem with the given name exists in this M&C system. In this case an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/treeview/{mncName}

Replaces the tree definition for a given M&C system with a new version supplied by the client. Echoes the tree definition for this M&C system after the request has been processed.

Parameters:

Parameter	Description
mncName	The name of the M&C for which the tree definition shall be replaced.

Expected Payload: A TreeViewNode document containing the user defined part tree branch for the given M&C, starting with the MNCNODE node for this M&C. Only the SUBSYSTEM children of this node are processed, if the TReeViewNode has a DEVICELIST child, this is ignored.

Replied Payload: A TreeViewNode document containing the tree branch for the given M&C, starting with the MNCNODE node for this M&C. This is the tree view branch after the request has been processed, it includes the DEVICELIST for this M&C.

Return Codes:

Code	Description
200	OK, the requested TreeViewNode document is returned.
404	The requested M&C system does not exist or is actually offline. In this case an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.37 /api/v1/debug

This API end point lets you send debug commands to the (already opened) debug terminal of a M&C.

Supported HTTP methods: POST, HEAD, OPTIONS

POST /api/v1/debug/{mncName}

Sends one line containing a debug command to the debug terminal of the given M&C. The websocket connection for the debug terminal must already be open to make the command work. Echoes the original command after the request has been processed.

Parameters:

Parameter	Description
mncName	The name of the M&C to send the debug command to.

Expected Payload: A DebugMessage document containing the line with the command to send.

Replied Payload: A copy of the DebugMessage which has been sent.

Return Codes:

Code	Description
200	OK, the echoed DebugMessage document is returned.
404	The requested M&C system does not exist, is actually offline or another user is already connected to the debug terminal at this M&C. In this case an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.38 /api/v1/redundancy

This API end point lets you control or interrogate the redundancy properties for redundant M&Cs.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/redundancy/{mncName}

Queries the state of the redundancy control logic for the given M&C

Parameters:

Parameter	Description
mncName	The name of the M&C to query.

Expected Payload: none.

Replied Payload: A RedundancyState object reporting the redundancy properties of the M&C.

Return Codes:

Code	Description
200	OK, a RedundancyState document is returned.
400	The requested M&C system is not configured as a redundant pair. In this case an ApiError document is returned, describing details of the error.
404	The requested M&C system does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/redundancy

Queries the state of the redundancy control logic for all redundant M&Cs.

Parameters: none.

Expected Payload: none.

Replied Payload: A RedundancySummary object reporting the redundancy properties of all redundant M&Cs.

Return Codes:

Code	Description
200	OK, a RedundancySummary document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/redundancy/{mncName}

Sends a redundancy command to either switch a redundant M&C pair or to enable/disable the M&C redundancy.

Parameters:

Parameter	Description
mncName	The name of the M&C to send the redundancy command to.

Expected Payload: A RedundancyCmd document containing the command to send.

Replied Payload: A copy of the RedundancyCmd which has been sent.

Return Codes:

Code	Description
200	OK, the echoed RedundancyCmd document is returned.
404	The requested M&C system does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

8.2.39 /api/v1/restart

This API end point lets you send a restart command to a given M&C.

Supported HTTP methods: PUT, HEAD, OPTIONS

PUT /api/v1/restart/{mncName}

Sends a restart command to the given M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C to send the redundancy command to.

Expected Payload: A RestartCmd document with *cmd* set to 'RESTART'. With other values of *cmd* the restart command is ignored.

Replied Payload: A copy of the RestartCmd which has been sent.

Return Codes:

Code	Description
200	OK, the echoed RestartCmd document is returned.
400	Either the RestartCmd passed to the call did not contain cmd=RESTART or the requested M&C system is offline and cannot be restarted. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	The requested M&C system does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.40 /api/v1/devicesetup

This API end point lets read and write the device setup for a specific M&C.

Writing a device setup as a whole to the M&C requires a M&C restart to make the M&C read and interpret the changed setup. Hence this is to be considered a legacy operation which will be replaced by API calls to modify the device configuration of the M&C 'on the fly' without restarting it, as soon as these API calls are available.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/devicesetup/{mncName}

Get the device setup for the given M&C.

Parameters:

Parameter	Description
mncName	The name of the M&C to read the device setup from.

Expected Payload: none.

Replied Payload: A DeviceSetup document describing the device configuration of the given M&C.

Return Codes:

Code	Description
200	OK, a DeviceSetup document is returned.
404	The requested M&C system does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/devicesetup/{mncName}

Sends a new device configuration to the given M&C. The configuration will be saved as

'vlc.setup' on this M&C, replacing the existing configuration. The M&C will use this configuration after the next restart (see /api/v1/restart).

Parameters:

Parameter	Description
mncName	The name of the M&C to send the device setup to.

Expected Payload: The DeviceSetup document containing the new / modified device configuration.

Replied Payload: Echoes back the DeviceSetup which has been sent.

Return Codes:

Code	Description
200	OK, the echoed DeviceSetup document is returned.
404	The requested M&C system does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.41 /api/v1/drivers

This API end point returns a list of the available device drivers for a specific M&C.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/drivers

Get the list of the available device drivers. The list is fetched from the primary M&C.

Parameters: none

Expected Payload: none.

Replied Payload: An ItemList document containing the names of all device drivers available.

Return Codes:

Code	Description
200	OK, an ItemList document is returned.

Code	Description
400	The primary M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.42 /api/v1/protocols

This API end point returns a list of the available device communication protocols. The list is fetched from the primary M&C.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/protocols

Get the list of all available device communication protocols. The list is fetched from the primary M&C.

Parameters: none.

Expected Payload: none.

Replied Payload: An ItemList document containing the names of all device communication protocols available.

Return Codes:

Code	Description
200	OK, an ItemList document is returned.
400	The primary M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.43 /api/v1/preferredprotocols

This API end point returns a list of the preferred device communication protocols a particular device driver uses. The list is fetched from the primary M&C.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/preferredprotocols/{driverName}

Get the list of the preferred device communication protocols a particular device driver uses.

Actually a ***sat-nms*** devices driver defines exactly one preferred protocol, hence this list will always have exactly one element. Future ***sat-nms*** versions may permit to define multiple preferred protocols for a driver.

Parameters:

Parameter	Description
driverName	The name of the device driver to check.

Expected Payload: none.

Replied Payload: An ItemList document containing the names of the preferred device communication protocols of the given driver.

Return Codes:

Code	Description
200	OK, an ItemList document is returned.
400	The primary M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
404	The device driver this call refers to does not exist. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

8.2.44 /api/v1/filerecordings

This API end point returns the recorded data for a File-Recorder device

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/filerecordings/{mncName}/{deviceName}

Reads the recorded data from the given File-Recorder device

Parameters:

Parameter	Description
mncName	The name of the M&C to read the data from
deviceName	The name of the File-Recorder device to read the data from

Expected Payload: none.

Replied Payload: The recorded data in CSV format (text/plain). Columns are separated by comma characters, the first column contains the time stamp in 'YYYY-MM-DD HH:MM:SS' format (UTC). All other columns contain the recorded data. Example:

```
2023-02-16 09:12:38,28.3,,,
2023-02-16 09:13:39,28.4,,,
2023-02-16 09:14:39,28.5,,,
2023-02-16 09:15:38,28.4,,,
2023-02-16 09:16:38,28.5,,,
2023-02-16 09:17:38,28.3,,,
2023-02-16 09:18:38,28.4,,,
2023-02-16 09:19:38,28.4,,,
```

Return Codes:

Code	Description
200	OK, the requested file recorder data is returned.
400	The M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	Either the referred M&C or the device does not exists or the device is not a File-Recorder device. In this case an ApiError document is returned, describing details of the error.

8.2.45 /api/v1/filerecordersettings

Reads and stores the diagram settings for a given file recorder device.

Supported HTTP methods: GET, PUT, HEAD, OPTIONS

GET /api/v1/filerecordersettings/{mncName}/{deviceName}

Reads the diagram settings for a given file recorder device.

Parameters:

Parameter	Description
mncName	The name of the M&C to read the data from
deviceName	The name of the File-Recorder device to read the data from

Expected Payload: none.

Replied Payload: The diagram settings as a FRViewProperties document.

Return Codes:

Code	Description
200	OK, the requested file recorder data is returned.
400	The M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	Either the referred M&C or the device does not exists or the device is not a File-Recorder device. In this case an ApiError document is returned, describing details of the error.

PUT /api/v1/filerecordersettings/{mncName}/{deviceName}

Stores the diagram settings for a given file recorder device.

Parameters:

Parameter	Description
mncName	The name of the M&C to store the data to
deviceName	The name of the File-Recorder device to store the data for

Expected Payload: The diagram settings to store as a FRViewProperties document.

Replied Payload: Echoes back the stored data (after storing it at the destination M&C and reading it back from there).

Return Codes:

Code	Description
200	OK, the echoed back diagram settings document is returned.
400	The M&C is offline, data cannot be stored. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	Either the referred M&C or the device does not exists or the device is not a File-Recorder device. In this case an ApiError document is returned, describing details of the error.

8.2.46 /api/v1/acutargets

Reads the targets / satellites stored on a given ACU.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/acutargets/{mncName}/{deviceName}

Reads the targets / satellites stored on a given ACU.

Parameters:

Parameter	Description
mncName	The name of the M&C to read the data from
deviceName	The name of the device to read the data from. This may be either the name of the ACU device itself or the name of the Antenna-Management device controlling the ACU

Expected Payload: none.

Replied Payload: The target list of the queries ACU as a AcuTargetList document.

Return Codes:

Code	Description
200	OK, the requested file recorder data is returned.
400	The M&C is offline, cannot be queried. In this case anApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	Either the referred M&C or the device does not exists or the device does not provide a target list. In this case an ApiError document is returned, describing details of the error.

8.2.47 /api/v1/inventory

This API endpoint is used to inspect or modify the backend's inventory of items / devices.

Supported HTTP methods: GET, POST, PATCH, HEAD, OPTIONS

GET /api/v1/inventory/{itemId}

Gets the inventory item with the given ID.

Parameters:

Parameter	Description
itemId	The itemId of the item to get

Expected Payload: none.

Replied Payload: An InventoryItem record with the given ID

Return Codes:

Code	Description
200	OK, the requested InventoryItem document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/inventory/{itemId}/devices

Gets the list of InventoryDevice objects mapped to the given inventory item.

Parameters:

Parameter	Description
itemId	The itemId of the item to get

Expected Payload: none.

Replied Payload: An array of InventoryDevice records mapped to the item with the given ID

Return Codes:

Code	Description
200	OK, the requested InventoryDevice Array is returned.

Code	Description
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

GET /api/v1/inventory/{itemId}/devices/{deviceId}

Gets the InventoryDevice objejct with the given ID combination.

Parameters:

Parameter	Description
itemId	The itemId of the item to get
deviceId	The deviceId of the device to get

Expected Payload: none.

Replied Payload: An InventoryDevice record with the given ID combination.

Return Codes:

Code	Description
200	OK, the requested InventoryDevice document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/inventory

Creates a new InventoryItem entry in the database.

Parameters: none.

Expected Payload:An InventoryItem record containing the fields of the record to create. The following rules apply:

- Fields which are null or missing are set to 'null' in the record.
- The field 'itemId' is ignored. The POST command creates a new record, the database

assigns a unique itemId to the created record.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.

Replied Payload: The created InventoryItem record

Return Codes:

Code	Description
200	OK, the modified InventoryItem document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

POST /api/v1/inventory/{itemId}/devices

Creates a new InventoryDevice entry in the database and attaches this to the given item.

Parameters:

Parameter	Description
itemId	The itemId of the item to add the new device to

Expected Payload:An InventoryDevice record containing the fields of the record to create. The following rules apply:

- Fields which are null or missing are set to 'null' in the record.
- The field 'deviceId' is ignored. The POST command creates a new record, the database assigns a unique deviceId to the created record.
- The field 'itemId' is ignored. The POST command always takes the the 'itemId' from the URL and sets this in the created record.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.

Replied Payload: The created InventoryItem record

Return Codes:

Code	Description

Code	Description
200	OK, the modified InventoryDevice document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

PATCH /api/v1/inventory/{itemId}

Modifies the inventory item with the given ID.

Parameters:

Parameter	Description
itemId	The itemId of the item to modify

Expected Payload:An InventoryItem record containing the fields to modify. The following rules apply:

- Fields which are null or missing are not changed in the record.
- To set a field to 'null' set it to an empty string.
- The field 'itemId' is ignored. The PATCH command modifies the record specified in the URI, the 'itemId' ofthis record never changes.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.

Replied Payload: The InventoryItem record after modification

Return Codes:

Code	Description
200	OK, the modified InventoryItem document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

Code	Description
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

PATCH /api/v1/inventory/{itemId}/devices/{deviceId}

Modifies the InventoryDevice object with the given ID combination.

Parameters:

Parameter	Description
itemId	The itemId of the item to modify
deviceId	The deviceId of the device to modify

Expected Payload:An InventoryDevice record containing the fields to modify. The following rules apply:

- Fields which are null or missing are not changed in the record.
- To set a field to 'null' set it to an empty string.
- The field 'deviceId' is ignored. The PATCH command modifies the record specified in the URI, the 'deviceId' of this record never changes.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.

Replied Payload: The InventoryDevice record after modification

Return Codes:

Code	Description
200	OK, the modified InventoryDevice document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/inventory/{itemId}

Deletes the inventory item with the given ID. As a side effect, allInventoryDevice and InventoryLogEntry objects referring to this inventory item are deleted as well.

Parameters:

Parameter	Description
itemId	The itemId of the item to delete

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the addressed InventoryItem has been deleted.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/inventory/{itemId}/devices/{deviceId}

Deletes the InventoryDevice obkect with the given ID combination.

Parameters:

Parameter	Description
itemId	The itemId of the item to delete
deviceId	The deviceId of the device to delete

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the addressed InventoryDevice has been deleted.

Code	Description
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

POST /api/v1/inventory/list

Gets a list of inventory items matching the filter information sent with the request.

Parameters: none

Expected Payload: An InventoryItem document containing the filter to be applied. Any fields in the document which are missing or null are intepreted as a wildcard. Specified fields must *all* match to include the item in the returned list. If a 'modified' timestamp is given in the filter description, it is interpreted as 'must be modified at this time or later'.

Replied Payload: An array of InventoryItem records fulfilling the filter spec. The list is sorted by modification time, oldest first. If no records match the filter, an empty list is returned.

Return Codes:

Code	Description
200	OK, the requested InventoryItem array is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	The backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/inventory/log/{entryId}

Gets the inventory log entry with the given ID.

Parameters:

Parameter	Description

Parameter	Description
entryId	The entryId of the log entry to get

Expected Payload: none.

Replied Payload: An InventoryLogEntry record with the given ID

Return Codes:

Code	Description
200	OK, the requested InventoryLogEntry document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No InventoryLogEntry with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/inventory/log

Adds a new InventoryLogEntry to the database.

Parameters: none.

Expected Payload:An InventoryLogEntry record containing the fields of the record to create. The following rules apply:

- log entries cannot be modified / rewritten. All fields must be supplied with their desired values.
- The field 'entryId' is ignored. The POST command creates a new record, the database assigns a unique itemId to the created record.
- The 'created' field is set to the time when the command is executed, a 'created' time specified in the supplied data is ignored.

Replied Payload: The created InventoryLogEntry record

Return Codes:

Code	Description
200	OK, the modified InventoryLogEntry document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	No InventoryLogEntry with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

POST /api/v1/inventory/log/list

Gets a list of inventory log entries matching the filter information sent with the request.

Parameters: none

Expected Payload: An InventoryLogEntry document containing the filter to be applied. Any fields in the document which are missing or null are intepreted as a wildcard. Specified fields must *all* match to include the entry in the returned list. If a 'modified' timestamp is given in the filter description, it is interpreted as 'must be created at this time or later'.

Replied Payload: An array of InventoryLogEntry records fulfilling the filter spec. The list is sorted by creation time, oldest first.

Return Codes:

Code	Description
200	OK, the requested InventoryLogEntry array is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	The backend does not support the inventory database. In this case anApiError document is returned, describing details of the error.

8.2.48 /api/v1/documents

This API endpoint is used to inspect or modify the backend's list of documents.

Supported HTTP methods: GET, POST, PATCH, HEAD, OPTIONS

GET /api/v1/documents/{documentId}

Gets the documents item with the given ID.

Parameters:

Parameter	Description

Parameter	Description
documentId	The documentId of the item to get

Expected Payload: none.

Replied Payload: An DocumentItem record with the given ID. The DocumentItem does not contain its 'fileContent' field, use the '/api/v1/documents/content/' API call to retrieve the document content.

Return Codes:

Code	Description
200	OK, the requested DocumentItem document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No DocumentItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/documents

Creates a new DocumentItem entry in the database.

Parameters: none.

Expected Payload:An DocumentItem record containing the fields of the record to create. The following rules apply:

- Fields which are null or missing are set to 'null' in the record.
- The field 'documentId' is ignored. The POST command creates a new record, the database assigns a unique documentId to the created record.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.

Replied Payload: The created DocumentItem record. The DocumentItem does not contain its 'fileContent' field, use the '/api/v1/documents/content/' API call to retrieve the document content.

Return Codes:

Code	Description
200	OK, the modified DocumentItem document is returned.

Code	Description
400	The file already exists. In this case the file is not written and an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No DocumentItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/documents/{documentId}

Modifies the documents item with the given ID.

Parameters:

Parameter	Description
documentId	The documentId of the item to modify

Expected Payload:An DocumentItem record containing the fields to modify. The following rules apply:

- Fields which are null or missing are not changed in the record.
- To set a field to 'null' set it to an empty string.
- The field 'documentId' is ignored. The PATCH command modifies the record specified in the URI, the 'documentId' of this record never changes.
- The 'modified' field is set to the time when the command is executed, a 'modified' time specified in the supplied data is ignored.
- If the field 'fileContent' is contained, the stored file gets rewritten with this content.
- If 'fileName' and 'fileContent' are changed at the same time, the old file is deleted before writing the new one.

Replied Payload: The DocumentItem record after modification. The DocumentItem does not contain its 'fileContent' field, use the '/api/v1/documents/content/' API call to retrieve the document content.

Return Codes:

Code	Description
200	OK, the modified DocumentItem document is returned.

Code	Description
400	A file with the new name already exists. In this case the file is not written and an ApiError document is returned, describing details of the error.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No DocumentItem with this ID exists or the backend does not support the documents database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

DELETE /api/v1/documents/{documentId}

Deletes the documents item with the given ID. This also deletes the file this record refers to.

Parameters:

Parameter	Description
documentId	The documentId of the item to delete

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
204	OK, the addressed DocumentItem has been deleted.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No DocumentItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.
500	DB is not writable. In this case an ApiError document is returned,describing details of the error.

GET /api/v1/documents/content/{documentId}

Gets the file content of the document item with the given ID.

Parameters:

Parameter	Description
documentId	The documentId of the item to get

Expected Payload: none.

Replied Payload: The file content of the data file this document record refers to.

Return Codes:

Code	Description
200	OK, the requested file is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No DocumentItem with this ID exists or the backend does not support the inventory database. In this case an ApiError document is returned, describing details of the error.

POST /api/v1/documents/list

Gets a list of documents items matching the filter information sent with the request.

Parameters: none

Expected Payload: An DocumentItem document containing the filter to be applied. Any fields in the document which are missing or null are intepreted as a wildcard. Specified fields must *all* match to include the item in the returned list. If a 'modified' timestamp is given in the filter description, it is interpreted as 'must be modified at this time or later'. The 'fileContent' field is ignored as a filter.

Replied Payload: An array of DocumentItem records fulfilling the filter spec. The list is sorted by file name, 'a' to 'z'. The DocumentItem records do not contain their 'fileContent' field, this API call is intended to list the items, not to to execute a bulk read of the documents.

Return Codes:

Code	Description
200	OK, the requested DocumentItem array is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.

Code	Description
404	The backend does not support the inventory database. In this case anApiError document is returned, describing details of the error.

8.2.49 /api/v1/thumbnail

This API call fetches a thumnail image from the backend. Thumbnail images are cached in the backend. If you subscribe for a thumbnail image via the websocket, the frontend only receives a messages which tells that a new thumbnail picture is available. The image itself then must be fetched with the `/api/v1/thumbnail` API call.

Supported HTTP methods: GET, HEAD, OPTIONS

GET /api/v1/thumbnail/{messageId}

Gets the thumbnail image for the given message ID (e.g. 'MNC-1.IRD-3.thumbnail') Please note, that the messageId must be subscribed or the API call will return a 404 Not Found because the backens has not subscribes for the thumbnail message at the M&C

Parameters:

Parameter	Description
messageId	The full message ID of the thumbnail parameter of the device

Expected Payload: none.

Replied Payload: An Thumbnail document containing the thumbnail image.

Return Codes:

Code	Description
200	OK, the requested Thumbnail document is returned.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	Not found. In this case an ApiError document is returned, describing details of the error.

8.2.50 /api/v1/backendinfo

This API endpoint gives the backend information for example name and role.

Supported HTTP methods: GET

GET /api/v1/backendinfo

Returns the BackendInfo data objects.

Parameters: none

Expected Payload: none

Replied Payload: BackendInfo data objects

Return Codes:

Code	Description
200	OK, returns a JSON document.
401	not logged in. In this case an ApiError document is returned,describing details of the error.

8.2.51 /api/v1/globalSettings

This API endpoint is used to get and or save global settings for the users.

Supported HTTP methods: GET, PATCH, HEAD, OPTIONS

GET /api/v1/globalSettings

Gets the saved settings if not Backend should retrun default values with setting keys.

Parameters: none

Expected Payload: none

Replied Payload: The list of stored and default settings as an array ofUISettings data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document.
401	not logged in. In this case an ApiError document is returned,describing details of the error.

PATCH /api/v1/globalSettings

Save setting in the Database. If *setting key* already exists it will overwrite the value.

Parameters: none

Expected Payload: The UISettings data object to store.

Replied Payload: The list of stored and default settings as an array ofUISettings data objects.

Return Codes:

Code	Description
201	OK, returns a JSON document.
401	not logged in. In this case anApiError document is returned,describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/globalSettings/{id}

Deletes the global settings with the given id.

Parameters:

Parameter	Description
id	The id of the settings to delete

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
202	ACCEPTED, Return Object ofUISettings.
401	Not logged in. In this case anApiError document is returned, describing details of the error.
404	No user setting with this username exists . In this case anApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

8.2.52 /api/v1/userSettings

This API endpoint is used to save or get user settings for the users.

Supported HTTP methods: GET, PATCH, HEAD, OPTIONS

GET /api/v1/userSettings

Gets the saved settings in data base if not Backend should retrun default values with setting keys.

Parameters: none

Expected Payload: none.

Replied Payload: The list of stored and default settings as an array ofUISettings data objects.

Return Codes:

Code	Description
200	OK, returns a JSON document.
401	not logged in. In this case anApiError document is returned,describing details of the error.

PATCH /api/v1/userSettings

Save user setting in the Database.

Parameters: NONE

Expected Payload: The UISettings data object to store.

Replied Payload: The list of stored and default settings as an array ofUISettings data objects.

Return Codes:

Code	Description
201	OK, returns a JSON document with all user settings.
401	not logged in. In this case anApiError document is returned,describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/userSettings/{id}

Deletes the user settings with the given id.

Parameters:

Parameter	Description

Parameter	Description
id	The id of the settings to delete

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
202	ACCEPTED, Return Object of UISettings.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No user setting with this username exists . In this case anApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

DELETE /api/v1/userSettings

Deletes the user settings with username. Username is take from token by the backend.

Parameters: none

Expected Payload: none.

Replied Payload: none.

Return Codes:

Code	Description
202	ACCEPTED, Return list of UISettings array list.
401	Not logged in. In this case an ApiError document is returned, describing details of the error.
404	No user setting with this username exists . In this case anApiError document is returned, describing details of the error.
500	DB is not writable. In this case anApiError document is returned,describing details of the error.

8.3 WebSocket Communication

The API provides a websocket at /msgs to update volatile data asynchronously. The data to be sent over the websocket is controlled with a subscription model. With the sat-nms Software, everything is about device parameters: Every device parameter has a unique ID, changes of this parameters are transported as messages having the id and the value of this parameter as properties. The websocket is used one-way: There are only messages sent from the backend server to the front end. The /api/v1/subscribe API call controls which messages / parameters shall be send over the websocket.

8.3.1 Creating WebSockets

Creating a websocket id a two-step procedure: First a websocket ID must be obtained. This is done using the /api/v1/makewebsocket API call. This call prepares a websocket which can be connected to. It returns an ID for the newly prepared websocket. The client must remember this ID during the session, it is required for all subsequent operations on this websocket.

The second step is to connect to this websocket. The URL for these websockets is **/msgs**, all connections share this. To identify which websocket to open, a query parameter defining the websocket ID must added to the HTTP URI when opening the websocket:

```
/msgs&satnmsWebsocketId=XXXXX
```

XXXXX has to be replaced by the 5-character websocket ID obtained with the /api/v1/makewebsocket API call.

The now connected websocket does not receive any data.

8.3.2 Subscribing For Messages

To receive data over the websocket, the data must be subscribed for. With the sat-nms Software, each device parameter and each type/range description has its unique message ID. For each message ID an explicit subscription must be done to get this parameter and its updates. The /api/v1/subscribe API call does this, either for a single message ID or for a list of IDs. Subscriptions are made for a certain websocket instance, hence the ID of the websocket must be supplied with the subscribe call.

Subscribed messages are sent asynchronously, each time when a change of the parameter is detected. It is not guaranteed, that a subscribe results immediately in a message sent over the websocket. Parameters may be in the state "unknown", specially in the first minutes after starting a M&C. Such a parameter will be sent when the first value becomes available.

The /api/v1/subscribe API call is also is used to unsubscribe messages using the DELETE HTTP method. It is recommended to unsubscribe messages for which there are no more updates needed.

Closing the websocket automatically unsubscribes all pending subscriptions. There is no need to do this explicitly before closing the session.

8.3.3 Interpreting WebSocket Data

The websocket transports text messages containing single JSON data objects. These objects all are Message objects. Parsing and interpreting the Message objects can be done along the*type* field in the message. The value of this field determines the data type and further content of the message:

Token	Message Type
VALUE	Parameter, contains an update for a parameter value
RANGE	Range, contains a data type an valid range definition for a parameter
PONG	This could be an echoed message used by the front end as a heartbeat (see Echo / Heartbeat Function below)

Range messages contain an additional *dataType* field which specifies the data type of the parameter belonging to this range definition. Depending on *dataType*, there will me more fields in the range message, specifying the valid range of a numeric parameter, the available choices for an enumeration and more. The table below list all defined data types:

Token	Data Type
INTEGER	IntegerRange
HEX	HexRange
FLOAT	DoubleRange
BOOLEAN	BooleanRange
ALARM	AlarmFlagRange
CHOICE	EnumRange
OBJECT	ObjectRange

8.3.4 Echo / Heartbeat Function

"Ping" messages on websocket protocol level sent to the websocket are answered with a "Pong" message. This can be used to implement a heartbeat mechanism at protocol level.

At application level this is possible as well. The backend's websocket implementation echoes all text messages received from the front end back to it. It is recommended to use Message data objects for this and setting *type* to a value not used by the backend.

8.3.5 Closing Websockets

When a websocket is closed, the backend server deletes all subscriptions made for this websocket. The websocket cannot be re-opened, the websocket ID obtained for the closed

websocket becomes invalid.

When there is no websocket opened in a session for 120 seconds, the backend server deletes the session, this is the way the backend server handles the case when the operator closes the browser window. *(not yet implemented)*

8.4 Debug Terminal Communication

The backend provides a relay mechanism to access the debug terminal at each M&C connected to the backend. While sending commands to the debug terminal is done with an API call, the messages showing in the terminal are sent to the front end through a websocket. The following paragraphs give an overview about this.

8.4.1 Opening A Debug Terminal

To open a debug terminal, the front end opens a websocket at the URI defined for this. It receives every line to be shown in the terminal window as one message on the websocket. The M&C allows only one client to connect to the debug terminal at a time, opening the websocket may fail if either the M&C is down or if another user is already connected to the debug terminal (either from the Web-UI or from a Java client).

The URI to connect to the debug terminal is `/debug&mncName=XXXXX`

Where XXXXX has to be replaced with the name of the M&C to connect to. Once opened, the websocket transports every line from the debug terminal as a DebugMessage data object to the front end.

8.4.2 Closing A Debug Terminal

While the websocket for a debug terminal is opened, this prevents other users from using this feature. Hence every debug terminal websocket should be closed by the front end as soon as it is no longer needed. Closing the websocket also closes the data connection the M&C debug terminal port and by this frees this resource.

8.4.3 Sending Debug Commands

Sending commands to the debug terminal is done with the/api/v1/debug API call. This also takes a DebugMessage data object payload, carrying the line to be entered at the debug terminal. /api/v1/debug API calls require a debug terminal websocket to the referenced M&C being already opened. The will fail if the websocket for this M&C is not open because this means that also the data connection to the M&C is not present.

8.4.4 M&C Redundancy Management

The backend provides a redundancy switching mechanism for M&C systems connected to it. A redundant pair of M&C systems share the M&C name, but the M&C systems have different IP addresses. The redundancy works asymmetrically (there is one primary and one backup M&C) and one-way (redundancy switch will never happen from backup to primary).

If the communication to the primary M&C breaks and cannot be re-established for some time, the backend stops the M&C service on the primary machine and starts it on the backup machine. From now on the backend connects to the IP of backup M&C to control it.

All configuration about this is done in the 'backend.properties' file. The second IP address for the backup M&C and parameters how long the backend shall retry to connect to the primary M&C before it does the switch over to the backup M&C.

The actual state of the redundancy for each M&C (pair) is reported through the /api/v1/mnclist API call. Each MncInfo record in the returned list defines a 'redundancy' field which tells about the actual state.

8.4.4.1 Redundancy Commands

While the general aspects of the redundancy are statically configured in the 'backend.properties' file, the backend provides a /api/v1/redundancy API call to control if the primary or the backup machine of a redundant pair shall be used. There are two commands which may be sent with this API call.

command	description
RESET	tells the backend to switch back to primary M&C. If the backend is already connected to the primary M&C, or if no redundancy is configured for this M&C, the 'RESET' command has no effect. If the backend cannot connect to the primary M&C for some time, it tries to switch over to the backup machine.
FORCE	forces a switch over to the backup M&C - even if the communication with the primary one works fine. Has no effect if no redundancy is configured or if the backend is already connected to the backup machine.

8.5 Data Models

This section describes the data models used as payload with the API calls mentioned above.

The data model descriptions appear in an order which groups related functions. An alphabetic list of all data models is listed below

- ActiveBackend
- AcuTarget
- AcuTargetList
- AlarmFlagRange
- ApiError
- ArrowElement
- AzElElement
- BackendInfo
- StreamKeyData
- BooleanRange

- ButtonElement
- ChannelData
- ChartElement
- ColorDefinition
- DatabaseVersion
- DebugMessage
- DeviceDefinition
- DeviceElement
- DeviceFrameDefinition
- DeviceFrameTab
- DevicePreset
- DeviceSetup
- DeviceThreadDefinition
- Dictionary
- DisplayElement
- DocumentItem
- DocumentList
- DoubleRange
- EditButtonElement
- EnumRange
- EventAck
- EventInfo
- EventLog
- EventReportRequest
- EventReport
- FaultElement
- FaultInfo
- FaultList
- FrameElement
- FRViewProperties
- FRViewTraceDescription
- FRViewPreset
- FRViewTraceScaling
- GaugeElement
- HexRange
- IconElement
- IntegerRange
- InventoryDevice
- InventoryItem
- InventoryLogEntry
- ItemList
- KeyValPair
- LatchingButtonElement
- LockButtonElement
- MCPElement
- Macro
- Message

- MncInfo
- MncList
- ObjectRange
- ParameterButtonElement
- ParameterElement
- Parameter
- PresetValue
- PresetVars
- DeviceVars
- RadioButtonElement
- Range
- RectElement
- RedundancyCmd
- RedundancyState
- RedundancySummary
- RestartCmd
- SatDbAntenna
- SatDbBeacon
- SatDbBeaconAttenuation
- SatDbI11Data
- SatDbPosition
- SatDbSatDetails
- SatDbSatOperator
- SatDbSatellite
- SatDbTLEData
- SatDbTableTracking
- SatDbTc
- SatDbTcAttenuation
- SatDbTleImport
- SatDbTm
- SatDbTmAttenuation
- SatDbState
- ScheduleEvent
- Schedule
- ScreenDefinition
- ScreenElement
- SpectrumElement
- SpectrumTrace
- StringRange
- SubscribeList
- SwitchElement
- TakeButtonElement
- TargetListElement
- TextElement
- Thumbnail
- TokenReply
- TrackingHistory

- TrackingPoint
- TreeViewNode
- UISettings
- UserList
- UserProperties
- WebsocketId
- XYChartElement

8.5.1 TokenReply

The TokenReply data model contains the data returned from a successful login or token refresh (API end point /token). The fields defined in this data model follow the OAuth2 recommendations.

Data Model

Key	Type	Value
access_token	String	The access token (JWT) to be added as 'Authorization: Bearer ...' header field with subsequent API calls.
refresh_token	String	The refresh token (JWT) to be used to refresh an expired access token with the /token API end point and *grant_type* set to 'refresh_token'.
token_type	String	Always 'JWT'
expires	Number	The number of seconds the access_token is valid

8.5.2 UserProperties

The UserProperties document contains some information about the user currently logged in. It is returned as a reply to the GET /api/v1/user call.

Data Model

Key	Type	Value
userName	String	The user (login) name.
fullName	String	The user's full name.
password	String	The user's password (encrypted).
groupList	String	A comma separated list of group identifiers this user is allowed to access.
privilege	Number	The user's privilege level (1..150)

Remarks

- The user's privilege level is very important for the front end as it specifies which user interface elements may be accessed by the user. With the sat-nms WebGUI the privilege level mechanism replaces the commonly used 'roles'. This works the following way:
  - Each active user interface element like an entry field, a drop down box has a privilege level defined. Predefined screens like standard device screens have these level set to standard values, with user defined screens each user interface element may be configured to an individual privilege level.
  - If the privilege level of the user is higher or equal to the level of the user interface element, he may change the parameter controlled by this element.
  - If the privilege level of the user is lower, he gets the actual value of the parameter displayed, but he may not change this value.
- The privilege level has a range from 1 to 150, commonly used values are 100 for standard operator access and 150 for admin privileges.

8.5.3 UserList

The UserList document contains the complete list of users known to the backend. It is returned as a reply to the GET /api/v1/users call.

Data Model

Key	Type	Value
users	Array	Contains the list of known users as an array ofUserProperties objects

8.5.4 ApiError

The backend server returns an ApiError document if something went wrong, i.e. The HTTP return code is not in the 200 range.

Data Model

Key	Type	Value
timestamp	String	The time and date when the event happened.
status	Number	The HTTP status code returned.
error	String	The textual description of *status*.
message	String	A message describing the reason of the error.
path	String	The path part of the URL which caused the error.

Remarks

- The *timestamp* has a format like `2020-01-16T09:40:48.079+0000`

- The fields *error* and *message* contain the same text in most cases.

8.5.5 MncList

The MncList is used with the /api/v1/mnclist API call to report the list of M&C systems managed by the backend.

Data Model

Key	Type	Value
mncList	Array	contains an array of MncInfo objects, each describing the properties of one M&C system manged by the backend. The first entry of the list is called the primary M&C, it is used to get the login data and the live event log. This (and only this) M&C has "primary" set true.

8.5.6 MncInfo

The MncInfo data model contains the properties of one entry in a MncList. It is used with the /api/v1/mnclist API call to report the list of M&C systems managed by the backend.

Data Model

Key	Type	Value
id	String	The ID / name of the M&C. This ID is used to identify the M&C in messages. See section Message below for details how the M&C ID is embedded in the message ID.
ipAddress	String	The IP address of the M&C server as defined in the backend configuration file.
connected	Boolean	The actual state of the connection to the M&C.
primary	Boolean	True marks this M&C as the primary one.
redundancy	String	Describes the state of the redundancy control for this M&C. Possible values are 'NONE' = no redundancy control configured for this M&C 'PRIMARY' = the backend connects to the primary IP address for the M&C 'BACKUP' = the backend connects to the backup IP address for the M&C

8.5.7 ActiveBackend

The ActiveBackend data model carries the name of the backend which actively controls M&C redundancy switching in a redundant backend configuration. It is used with the /api/v1/activebackend API call.

Data Model

Key	Type	Value
activeBackendName	String	The name of the backend which is or shall be the active backend

The name of a backend is defined in the 'backend.properties' file with the 'backend.name' key.

8.5.8 SubscribeList

The SubscribeList is used with the /api/v1/subscribe API call to define a list of message identifiers the front end wants to subscribe or to unsubscribe from.

Data Model

Key	Type	Value
subscribeList	Array	contains an array of strings, each string is on message ID to be subscribed / unsubscribed.

8.5.9 WebsocketId

The WebsocketId carries the ID of a newly created websocket instance. It is returned by the /api/v1/makewebsocket API call in the response body.

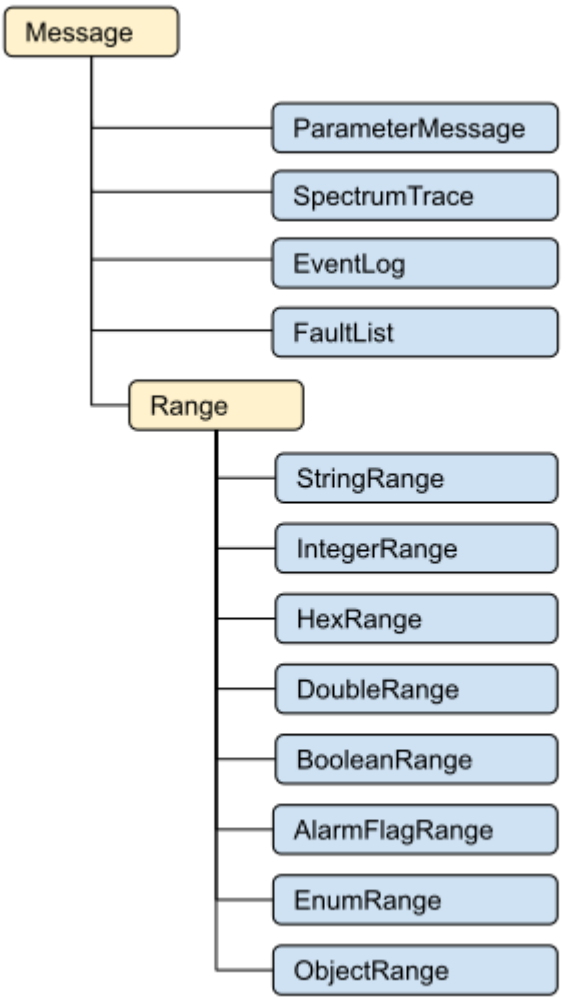
Data Model

Key	Type	Value
id	String	A newly created websocket ID. This is a unique 5-character string identifying the websocket for all further processing.

8.5.10 Message

With the sat-nms software, all volatile data gets exchanged as a Message. A message may carry a parameter like a value read from a device or a setting for this device. Beside this, data type and range information about parameters are exchanged as messages as well.

Because of this there are several flavors of messages defined, based of a hierarchical model derived from object oriented programming. The diagram below shows the known variants of Message as they depend on each other. Data models with yellow background do not exist in reality, they are defined as 'abstract base classes' which define the common parameters of their siblings.



Messages are used either with the /api/v1/peek and /api/v1/poke API calls or with the subscription model over a websocket connection.

The core property of a Message is its message ID. The message ID describes, which parameter of which device connected to which M&C server is addressed with the information of the message. The general format of a message ID is:

```
{M&C-Name}.{Device-Name}.{Parameter-Name}[.R]
```

The message ID is composed of at least three words with dots in between. The first word describes the M&C server to which the device is connected which is addressed by the second word. The third word identifies one parameter of this device, this identifier again may contain dots, if the parameter in the device are organized in a tree-like structure. Finally, the character sequence **.R** may be appended to the ID. This marks the message containing the range information about the parameter instead of the actual parameter value. Example:

```
MNC-1.DEVICE-3.parameter
```

Data Model

Key	Type	Value
id	String	The message ID associated with this message.
type	String	The message type (see below).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ' (UTC)

Defined Message Types

Token	Data Type
VALUE	A Parameter message.
RANGE	A Range message.
SPECTRUM	A SpectrumTrace message. This message may not be sent with a /api/v1/poke call, it is read-only from the front end's point of view.
EVENTLOG	An EventLog message. This message may not be sent with a /api/v1/poke call, it is read-only from the front end's point of view.
FAULTLIST	A FaultList message. This message may not be sent with a /api/v1/poke call, it is read-only from the front end's point of view.
PONG	Echo reply (PONG is only an example, the front end may send any message type other than *VALUE* or *RANGE*, the backend will echo the message as it is received.)

Message IDs of Range messages always end with **.R** - this is the way the underlying ***sat-nms*** M&C software marks these messages.

8.5.11 Parameter

A Parameter message carries a value to or from a device controlled by the M&C server. When sent from the UI to the M&C server, the Parameter message commands a new value to be set at the device. When sent from the M&C server to the UI, the message informs about a change of the parameter. This applies to read-only parameters like state flags or measurement values and to settings-type parameters as well.

Data Model (extends Message)

Key	Type	Value
id	String	The message ID (see Message)

Key	Type	Value
type	String	The message type (always **VALUE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
val	String	The value of the parameter, coded as a String.

The value contained in a Parameter message (*val*) may be of different types. The Range of the parameter defines this type, strictly spoken the *dataType* field in the Range message. For simplicity, all data types are coded as a string value in the Parameter message. The table below specifies, in which way parameter values are coded for all defined *dataType* flavors:

Range *dataType*	Coding in the *val* field
TEXT	UTF8 coded String.
INTEGER	Decimal number, consisting of digits 0..9
HEX	Decimal (!) number, consisting of digits 0..9
FLOAT	Floating point number with decimal point
BOOLEAN	Either **true** or **false** (all lower case)
ALARM	Either **true** or **false** (all lower case)
CHOICE	The selected choice as a UTF8 coded string. Please note, case is significant with choices. The values **ON** and **On** are treated as different ones.
OBJECT	ObjectRange parameter are not supported with this version of the API. Writing an ObjectRange parameter to the M&C is ignored, when queries an ObjectRange parameter always reports an empty string in *val*.

8.5.12 Range

A Range message contains the type definition and an optional specification for a range/limit validation for numeric parameters. The data model definition for Range is abstract, which means it never will be used in practice, only the data models derived from this will be used in the API.

Data Model (extends Message)

Key	Type	Value
id	String	The message ID (see Message)

Key	Type	Value
type	String	The message type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	A token defining the data type this Range object describes. Depending on *dataType*, there are more parameters present in the Range definition.
disabled	Bool	True tells the front end that this parameter is currently not in use. No value shall be displayed for this parameter, even if a corresponding Parameter message has been received. Any decorations like frame or descriptive label shall be displayed grayed/faded in order to show this state to the operator.
readonly	Bool	This parameter is for display only, the operator may not change it.

Defined Data Types

Token	Data Type
TEXT	StringRange
INTEGER	IntegerRange
HEX	HexRange
FLOAT	DoubleRange
BOOLEAN	BooleanRange
ALARM	AlarmFlagRange
CHOICE	EnumRange
OBJECT	ObjectRange

Remark: Range objects are also used in the PresetVars list of device driver variables. In this case *messageId* does not contain a fully qualified message ID, but the name of the variable.

8.5.13 StringRange

A StringRange parameter carries a free text.

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)

Key	Type	Value
type	String	The message data type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **TEXT** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range

8.5.14 IntegerRange

An IntegerRange parameter carries an integer number. Internally the value is represented by a signed 64-bit number (data type *long*).

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message data type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **INTEGER** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range
checkLimits	Boolean	true = the front end must validate any entry for this parameter to be in the range *min ... max*. Invalid entries must be rejected, no values shall be sent to the server if outside the given range.
min	Number	The minimum value to be accepted with *checkLimits*=true
max	Number	The maximum value to be accepted with *checkLimits*=true
unit	String	A unit string to be displayed right of the parameter value (e.g. "MHz" for a frequency)

8.5.15 HexRange

A HexRange parameter carries an integer number. Internally the value is represented by a signed 64-bit number (data type *long*). HexRange is much like IntegerRange with the only difference, that values are printed at the UI in hexadecimal notation (no prefix like '0x' or '#') and user entries are expected in the same format.

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **HEX** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range
checkLimits	Boolean	true = the front end must validate any entry for this parameter to be in the range *min ... max*. Invalid entries must be rejected, no values shall be sent to the server if outside the given range.
min	Number	The minimum value to be accepted with *checkLimits*=true
max	Number	The maximum value to be accepted with *checkLimits*=true
unit	String	A unit string to be displayed right of the parameter value (e.g. "MHz" for a frequency)

8.5.16 DoubleRange

A DoubleRange parameter carries a floating point value. Internally floating point values are represented by 64-bit floating point values (data type *double*, that gave the name for the DoubleRange).

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message data type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **FLOAT** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range

Key	Type	Value
checkLimits	Boolean	true = the front end must validate any entry for this parameter to be in the range *min ... max*. Invalid entries must be rejected, no values shall be sent to the server if outside the given range.
min	Number	The minimum value to be accepted with *checkLimits*=true
max	Number	The maximum value to be accepted with *checkLimits*=true
prec	Number	The precision (number of digits following the decimal point). Details are given in the paragraph **Number Formatting** below
unit	String	A unit string to be displayed right of the parameter value (e.g. "MHz" for a frequency)

Number Formatting

FLOAT variables are displayed with a fixed precision. The *prec* parameter defines how many digits right of the decimal point shall be displayed. Values of *prec* above 100 define a scientific formatted floating point with *prec - 100* digits precision (e.g. '0.123E-2' for *prec=103*)

8.5.17 BooleanRange

A BooleanRange parameter carries a BOOL value. It may be one of the values *true* or *false*.

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **BOOL** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range

8.5.18 AlarmFlagRange

The AlarmFlagRange describes a sat-nms ALARM parameter. Like the BOOL parameter may be *true* (alarm) or *false* (no alarm). The AlarmFlagRange defines a descriptive text for the alarm flag which can be displayed beside the actual state.

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message data type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **ALARM** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range (always *true* with alarm flags)
description	String	A short description of the ALARM

8.5.19 EnumRange

The EnumRange describes a parameter which' value can be one of a given set of values. An UI typically implements this parameter type as a drop down box or as a list box which allows a single selection.

Data Model (extends Range)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **CHOICE** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range
choices	Array	An array of string containing the choices for this parameter

8.5.20 ObjectRange

An ObjectRange describes a parameter carrying binary data, e.g. A spectrum analyzer trace. Special software is required to decode the data contained.

Data Model (extends Range)

Key	Type	Value

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message data type (always **RANGE**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
dataType	String	Always **OBJECT** (see Range)
disabled	Bool	Inherited from Range
readonly	Bool	Inherited from Range

8.5.21 SpectrumTrace

A SpectrumTrace message contains the spectrum trace data distributed by a CSM-Spectrum-Analyzer device. The spectrum trace is much like a read-only parameter (it may not be commanded to the M&C), instead of a single value it carries an array of numeric values.

The array elements represent the spectrum trace, all elements are integer numbers describing the point position in pixels from the top of the display downwards. The length of the trace depends on the particular spectrum analyzer model, common trace lengths are 501 or 601 points. The first array element is the leftmost point (at *centerFrequency-frequencySpan/2*), the last array element is the is the rightmost point (at *centerFrequency+frequencySpan/2*).

The point positions in the array (array index, element value) refer to the native size of the spectrum analyzer display as read out by the driver. This spectrum display size in pixels may be read from the spectrum analyzer device as the 'info.screen' variable. The spectrum analyzer widget on the screen may however re-scale the display to any size requested.

Data Model (extends Message)

Key	Type	Value
id	String	The message ID (see Message)
type	String	The message type (always **SPECTRUM**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
trace	Array of Number	The spectrum trace, as an array of integer values, describing the point position in pixels from the top of the display downwards.

8.5.22 TrackingPoint

A TrackingPoint message contains pointing data of an antenna tracking controller for one tracking step. An array of TrackingPoint elements makes up the TrackingHistory which is

described below

Data Model

Key	Type	Value
time	String	A time stamp telling when this tracking point was recorded. The format follows ISO 8601, example: `2021-03-26T08:02:30Z`, time zone is always UTC.
apos	Number	The azimuth pointing of the antenna after the tracking step.
epos	Number	The elevation pointing of the antenna after the tracking step.
blev	Number	The beacon level after the tracking step.
asucc	Boolean	True = the peaking process of the azimuth axis was successful.
apeak	Number	The azimuth peak position evaluated during the tracking step. Only meaningful if *asucc* is true.
esucc	Boolean	True = the peaking process of the elevation axis was successful.
epeak	Number	The elevation peak position evaluated during the tracking step. Only meaningful if *esucc* is true.

8.5.23 TrackingHistory

A TrackingHistory message contains the tracking memory of an antenna tracking controller. Actually, only the SatService ACU provides this data. The TrackingHistory message is read-only, meaning it may not be commanded to the M&C.

Data Model

Key	Type	Value
trace	Array of TrackingPoint	The tracking memory. The tracking points are ordered by time in the array, the first element refers to the oldest tracking point.

8.5.24 EventLog

An EventLog message carries the up to 24 most recent events that occurred in one of the M&C systems managed by the backend. The backend collects the events from the M&C systems and combines them to this list. The backend updates this message whenever a new message is added to the log, but at a maximum rate of one message per second.

To subscribe for the EventLog message, a/api/v1/subscribe API call must be made for the message ID `{Primary-M&C-Name}.SYSTEM.eventLog` where {Primary-M&C-Name} is the name / ID of the M&C reported with the /api/v1/mnclist API call with the "primary" key set true.

Data Model (extends Message)

Key	Type	Value
id	String	The message ID. This is always the message ID described above. (see Message)
type	String	The message type (always **EVENTLOG**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
events	Array	An array of EventInfo objects representing the recent events which occurred. This array has not more than 24 elements, directly after system start the array may be shorter or even empty if no events have been collected yet.

8.5.25 EventReport

An EventReport contains a list of EventInfo objects. The EventReport is the reply of the backend for a /api/v1/eventreport call when sent as a POST.

Data Model

Key	Type	Value
events	Array	An array of EventInfo objects.

8.5.26 EventReportRequest

The EventReportRequest specifies the filters to be applied when generating an EventReport. It has to be sent with an /api/v1/eventreport POST call.

Data Model

Key	Type	Value
from	String	Specifies the start of the time range of the report. Must be formatted following ISO 8601, example: `2021-03-26T08:02:30Z`, time zone is always UTC.
to	String	Specifies the end of the time range of the report. Must be formatted following ISO 8601, example: `2021-03-26T08:02:30Z`, time zone is always UTC. May be *null* if *length* is not zero.
length	Number	The length of the time range of the report in hours. If this value is zero, the report length is determines as the difference *to* - *from*. If the value is not *null*, the *to* value is ignored and *length* is used as the report length.

Key	Type	Value
mnc	String	The M&C name filter. Only events containing this text in their *source1* (M&C name) field are included in the report. If*mnc* is *null*, all events pass this filter.
device	String	The device name filter. Only events containing this text in their *source2* (device name) field are included in the report. If*device* is *null*, all events pass this filter.
host	String	The host name filter. Only events containing this text in their *origin1* (host name) field are included in the report. If *host* is *null*, all events pass this filter. Please note that only parameter change events have a host name set, other events will never match this filter.
user	String	The user name filter. Only events containing this text in their *origin2* (user name) field are included in the report. If *user* is *null*, all events pass this filter. Please note that only parameter change events have a user name set, other events will never match this filter.
maxlen	Number	The maximum length of the report (number of event messages). If more events than this number match the filter settings, only the oldest *maxlen* events of these will be contained in the report. If maxlen is null, the server side default for the maximum report length is used.
pri	String	The event priority filter. Must contain one of the following: ALL = include all events (no filter) INFO = include the events with priority INFO or higher INFO-ONLY = include the events with exactly priority INFO WARNING = include the events with priority WARNING or higher WARNING-ONLY = include the events with exactly priority WARNING FAULT = include the events with priority FAULT or higher FAULT-ONLY = include the events with exactly priority FAULT
text	String	The message text filter. Only messages which contain the given text are included in the report. If *text* consists of multiple words separated by space characters, the message text must contain all these words in arbitrary sequence. If *text* is *null*, all events pass this filter.

8.5.27 EventAck

The EventAck tells the backend which events in the event log shall be acknowledged. It is sent with a POST call to /api/v1/eventack.

Data Model

Key	Type	Value
ackAll	Boolean	Selects if a single event shall be acknowledged (false) of if all pending events shall be acknowledged (true).
event	EventInfo	The event to be acknowledged. *event* is ignored if *ackAll* is true.

8.5.28 EventInfo

An EventInfo contains the properties of one event within an EventReport or an EventLog message.

Data Model

Key	Type	Value
id	Number	A unique numeric identifier for this record. The event id is required to acknowledge a particular event.
pri	Number	The event priority coded as a one digit number 0 = suppressed, the event shall not be shown 1 = informational 2 = fault 3 = alarm 4 = warning
nak	Boolean	*(needs to be acknowledged)* This reads true for unacknowledged fault events.
msg	String	The event message text.
t1	String	*(time1)* A time stamp defining the time when the event was detected. The format follows ISO 8601, example: `2021-03-26T08:02:30Z` , time zone is always UTC.
t2	String	*(time2)* A time stamp defining the time when the event was stored in the event database. The format follows ISO 8601, example: `2021-03-26T08:02:30Z` , time zone is always UTC.
s1	String	*(source1)* The name / id of the M&C which generated this event.
s2	String	*(source2)* The name of the device which generated this event.
o1	String	*(origin1)* The name of the originator. Used with parameter change events to tell who commanded the change. May be a user name or in case of automatic parameter changes the name of the device which caused the change.
o2	String	*(origin2)* The host name / IP address from where a parameter change was commanded.

8.5.29 FaultList

A FaultList message carries the list of active faults and warnings which are pending at a given M&C. The backend updates this list whenever a fault changes at this M&C but at a maximum rate of one message per second.

To subscribe for the FaultList message, a/api/v1/subscribe API call must be made for the message ID `{M&C-Name}.SYSTEM.faultList` where {M&C-Name} is the name / ID of the M&C of interest.

Data Model (extends Message)

Key	Type	Value
id	String	The message ID. This is always the message ID described above. (see Message)
type	String	The message type (always **FAULTLIST**, see Message).
time	String	Timestamp in format 'YYYY-MM-DDTHH:MM.SSZ', see Message).
faults	Array	An array of FaultInfo objects representing list of actually pending faults and warnings at the given M&C.

8.5.30 FaultInfo

A FaultInfo contains the properties of one fault of warning reported in aFaultList message.

Data Model

Key	Type	Value
time	String	A time stamp telling when this fault changed its state. The format follows ISO 8601, example: `2021-03-26T08:02:30Z` , time zone is always UTC.
src	String	The name of the device which generated this event.
pri	Number	The event priority coded as a one digit number 0 = suppressed or device out-of-service, the fault shall not be shown 1 = informational 2 = fault 3 = alarm 4 = warning
msg	String	The fault message text.

8.5.31 DeviceFrameDefinition

A DeviceFrameDefinition document defines tabs to be shown in a sat-nms device screen. It resembles the content of a file in the *dframes* directory of the ***sat-nms*** M&C software.

DeviceFrameDefinition documents are returned by a GET /api/v1/dframes/{name} call.

Data Model

Key	Type	Value
name	String	The file name of the dframe definition
allowPresets	Boolean	true = the UI shall show the load/save preset buttons for this dframe
presetPrivilege	Number	the privilege level required to launch the preset load/save dialogs. This only is meaningful with *allowPresets=true*
tabs	Array	Contains a list of DeviceFrameTab objects, each describing one tab of the device frame

8.5.32 DeviceFrameTab

A DeviceFrameTab document defines one tab to be shown in a***sat-nms*** device screen. It appears as part of the DeviceFrameDefinition data object.

Data Model

Key	Type	Value
icon	String	The name of the icon to be shown in the tab header
dscreen	String	The name of the dscreen to be shown in this tab
description	String	A description of what is shown in this tab, the Java UI shows this as a mouse over tooltip

8.5.33 ScreenDefinition

A ScreenDefinition document defines the layout of a screen / page to display. The document contains some global properties of the screen and an array of ScreenElement objects, which each define one UI widget with its properties.

With the sat-nms software there are two general types of screen definitions: 'user defined screens' and 'device screens'. While the first type may contain widgets which show parameters of any device controlled by the sat-nms M&C are 'device screens' bound to one particular device. Device screens are returned by a GET /api/v1/dscreens/{name} call, user screens by a GET /api/v1/uscreens/{name} call.

Data Model

Key	Type	Value
name	String	The file name of the screen definition
deviceRelative	Boolean	true = contains no device IDs, the front end application must add the device ID from the context of the screen
width	Number	Width of the screen (pixels in the Java client)
height	Number	Height of the screen (pixels in the Java client)
bgImage	String	Name of a background image to draw in the screen. An empty value states that there is no background image.
noEditTake	Boolean	true = exclude this screen from global edit/take if this feature has been set for the UI.
elements	Array	Contains ScreenElement objects, the list of the screen elements contained in this screen.

8.5.34 ScreenElement

A ScreenElement object describes the properties of one UI widget contained in a ScreenDefinition. This comprises the type of widget, its location and size and many more parameters which depend on the type of widget this ScreenElement defines. This way ScreenElement is kind of an abstract definition or 'base class' in terms of object oriented programming. ScreenElement defines the parameters which are common to all types of screen elements.

Data Model

Key	Type	Value
type	String	The type of the screen element. See the list of screen element types below for details.
xpos	Number	X-position of the upper left corner of the element in the screen (pixels in the Java client)
ypos	Number	Y-position of the upper left corner of the element in the screen (pixels in the Java client)
width	Number	Width of the element (pixels in the Java client)
height	Number	Height of the element (pixels in the Java client)

As mentioned above, a ScreenDefinition will never contain a ScreenElement with only the parameters shown in the table above. All ScreenElement objects will be of a certain screen element type and will contain all parameters defines for this element type. The parameters described for ScreenElement will be always included.

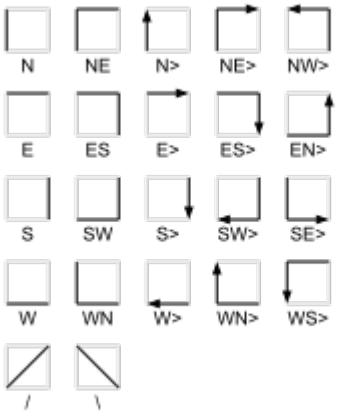
List of screen element types:

Element Type	Description
ArrowElement	Draws a horizontal/vertical line or arrow.
AzElElement	A chart showing the tracking history of an antenna controller as a point cloud in an elevation over azimuth coordinate system.
ButtonElement	Defines a button which launches another screen, e.g. for detail views.
ChartElement	A strip chart element, displaying a numeric parameter as an y/t diagram that automatically advances with 1 pixel / second.
DeviceElement	Places an icon into the screen which represents a device. This icon will display the device's operating/fault state by it's color / shape.
DisplayElement	A parameter display field which does not allow the parameter to be edited.
EditButtonElement	Places an EDIT button into the screen, implicitly forcing the EDIT/TAKE operating method for this screen instead of changing each parameter independently.
FaultElement	A special display element to display a fault flag. It shows the textual description of the fault and it's state in an entry field frame. The right mouse button shows a context menu to change the fault's priority
FrameElement	Draws a sunken 3D frame, may be used to group parameters.
GaugeElement	A gauge element, displaying a numeric parameter as a horizontal bar.
IconElement	Places an icon (PNG, GIF or JPG image) into the screen. Optionally the icon can be programmed to change with a parameter value.
LatchingButtonElement	A button which displays/controls a 2-state parameter using it's pressed state.
LockButtonElement	A button to control the lock state for exclusive operation for a number of devices.
MCPElement	The MCP display element integrates the measurement display of a spectrum analyzer device in multi channel measurement mode in a user screen.

Element Type	Description
ParameterButtonElement	A button which sends a certain parameter value when pressed.
ParameterElement	Either a parameter entry field or a drop down box, depending on the type of parameter.
RadioButtonElement	A parameter entry field specially for CHOICE parameters.
RectElement	Draws a rectangle.
SpectrumElement	The spectrum display element integrates the spectrum display of a spectrum analyzer device in a user screen.
SwitchElement	Like the device icon, but additionally displays the actual position of a switch (Meant to be used for block diagrams showing the true signal path.
TakeButtonElement	Places a TAKE button into the screen.
TargetListElement	The ODM Target List element shows the list of targets of a SatService-ACU-ODM antenna controller device. It permits to recall, save or delete target definitions of this type of antenna controller. It is specialized to this antenna controller, does not support other types.
TextElement	Displays a single line of text.
ThumbnailElement	Displays a thumbnail image fetched directly from a video processing device (encoder, decoder, gateway)
XYChartElement	This element shows the relation of two numeric variables in an X/Y diagram, featuring a trace which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.

8.5.35 ArrowElement

The ArrowElement draws a horizontal and/or a vertical line and optionally an arrowhead. The line's color is selectable, also may follow a parameter value. Strictly spoken the ArrowElement is a rectangle with only one or two sides drawn. The parameter *arrowCode* defines which sides of the rectangle shall be drawn and if an arrow shall be placed at the end of the line. The figure below shows all arrow codes defined:



Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ArrowElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to. Is only relevant if *variableLineColor* reads *true*.
arrowCode	String	A 1..3 character code defining the line/arrow outline. See the figure above which arrow codes are possible.
color	String	The color used for the line / arrow.
variableLineColor	Boolean	true = set the line color from the value received from the parameter addressed by *id*.
useColorTranslation	Boolean	use the colors[] translation
colors	Array	of ColorDefinition objects. Defines how to translate values of the *id* parameter to color values if *useColorTranslation* reads *true*.

Variable Line Color

With *variableLineColor=true* the ArrowElement will change its line color depending on the value of the parameter addressed by *id*. This way the line can be used as a status indicator, e.g. in a block diagram signalling "the signal goes actually this way". The way the ArrowElement interprets the parameter value depends on the value of *useColorTranslation*.

If *useColorTranslation=false*, the ArrowElement tries to decode the line color directly from the parameter value. First it does the following tests on the parameter value (not case sensitive):

Parameter Value	**Line Color And Thickness**
ends with **BOLD**	The line is drawn thicker than normal
starts with **BLACK**	The line is drawn with this color
starts with **WHITE**	The line is drawn with this color
starts with **RED**	The line is drawn with this color
starts with **BLUE**	The line is drawn with this color
starts with **GREEN**	The line is drawn with this color
starts with **YELLOW**	The line is drawn with this color
starts with **GRAY**	The line is drawn with this color
contains **TRUE**	If the message ID identifies the parameter as an alarm flag (the ID contains 'fault'), the line is drawn **RED-BOLD**, for other parameters it is drawn **GREEN-BOLD**
contains **FAULT**	The line is drawn **RED-BOLD**
starts with **ON**	The line is drawn **GREEN-BOLD**

If none of the above conditions apply, the ArrowElement tries to interpret the parameter value as a hex coded color (#RRGGBB). If this also fails, the standard line color defined in *color* is used.

If *useColorTranslation=true*, the ArrowElement uses the ColorDefinition table in *colors[]* to decode the line's color and thickness.

8.5.36 ButtonElement

The ButtonElement creates a button which launches another user interface screen if pressed.

The screen to be launched may be another user defined screen or a predefined one.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ParameterButtonElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
privilege	Number	The privilege level required to make a button click send a value
label	String	A label shown on the button
icon	String	An icon shown on the button
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
action	String	The action to perform if the button is clicked (see below)
par1	String	A parameter that applies for the action to perform. The meaning of this field depends on the *action* selected (see below)
par2	String	A second parameter that applies for the action to perform. The meaning of this field depends on the *action* selected (see below)
par3	String	A third parameter that applies for the action to perform. The meaning of this field depends on the *action* selected (see below)
variableBackgroundColor	Boolean	true = use a variable background color
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

The *action* field of the ButtonElement defines what the button will do when clicked by the operator. The list below shows all known values for *action*, the meaning of this and a description of the parameters *par1* and *par2* which will have different meanings for particular action.

CHILD-SCREEN

Launches a new browser tab or window showing the user screen referenced with *par1*.

- *par1:* The name of the user screen to show.
- *par2:* null
- *par3:* null

REPLACE-SCREEN

Replaces the actual user screen by the one referenced with *par1*.

- *par1:* The name of the user screen to show.
- *par2:* null
- *par3:* null

LOAD-PRESET

Launches a "Load Preset" dialog which lets the operator select and apply a device preset from a list of presets which are defined for this particular type of device. Device presets are local to each M&C instance, have to be loaded and applied from there.

- *par1:* The name of the device to which the preset shall be applied to. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MYDEVICE` (must be set in the screen editor this way).
- *par2:* The name of the driver of this device.
- *par3:* An option search pattern to filter the list of displayed presets. All presets containing the given string (not case sensitive compare) shall be shown. If *par3* is null, all preset for the given device / driver combination shall be shown.

TRACK-VIEW

Launches a tracking view window. This window shows the tracking history of a given antenna controller device. Not all tracking controller devices are capable to report their tracking history.

- *par1:* The name of the antenna controller device for which the tracking history shall be shown. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MYACU` (must be set in the screen editor this way).
- *par2:* null
- *par3:* null

AZEL-VIEW

Launches a Az/El view window. This window shows the tracking history of a given antenna controller device as a cloud of dots in a azimuth over elevation coordinate system. Not all

tracking controller devices are capable to report their tracking history.

- *par1:* The name of the antenna controller device for which the tracking history shall be shown. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MYACU` (must be set in the screen editor this way).
- *par2:* null
- *par3:* null

FREC-VIEW

Launches a File-Recorder view window. This window shows the data recorded by the File-Recorder device referenced with *par1* or the live data provided by this device.

- *par1:* The name of the File-Recorder device. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MY-FREC` (must be set in the screen editor this way). In the device screen of the file recorder, the special device name "." denotes *this* device.
- *par2:* The file recorder view preset number (0..7) to be applied. May be null, in this case no stored settings are applied.
- *par3:* null

SPECTR-VIEW

Launches a Spectrum Display window. This window in fact is a device screen of the CSM-Spectrum-Analyzer device.

- *par1:* The name of the spectrum analyzer device. The device name has the name of the M&C prepended where it is controlled. Example: `MYMNC.MY-FREC` (must be set in the screen editor this way).
- *par2:* A comma separated list of message-id/value pairs. Within each pair the message-id is separated from the value by one space character. Message ids are fully qualified, starting with the M&C name (must be set in the screen editor this way). The Spectrum Display window shall parse this list and send every message defined in the list with a poke call to the backend. This macro-like function is used to initialize the spectrum analyzer or to switch its input when the window is launched.
- *par3:* null

BROWSER-VIEW

Opens a new Browser window and displays a given URL in this window. This function is used to invoke the sat-nms online help and to launch the Web-GUI of certain devices.

- *par1:* The URL to show. Before launching the browser window, some replacements have to be done on the URL string:
  - If *par1* is a string consisting only of 4 decimal digits, this is a sat-nms online help topic number and the string must be expanded to the full URL from where this topic can be loaded by the browser.
  - If the ButtonElement is part of a device screen and the URL contains '@' characters, they have to be replaced with the (IP-) address of the device. A double '@@'

escapes this behavior and gets replaced by a single '@' in the URL string.

- *par2:* null
- *par3:* null

VIDEO-VIEW

Launches a VideoLAN video player to show the video stream from a surveillance camera controlled by a M&C. The VIDEO-VIEW ButtonElement may only occur in device screens, the IP address of the camera has to be taken from the address_ parameter of the device.

- *par1:* null
- *par2:* null
- *par3:* null

ROBOT-IMPORT

Launches a Robot Import screen. This screen lets the operator select a Pointing-Robot file from the local PC, the file gets converted to sat-nms format an then transferred to the M&C.

- *par1:* null
- *par2:* null
- *par3:* null

TREE-NAVIGATE

In a tree view UI this button navigates in the tree to the tree path referenced with*par1*. As the tree view UI with the WebUI is still t.b.d., this description should be considered as preliminary.

- *par1:* The tree view path to navigate to.
- *par2:* null
- *par3:* null

UNKNOWN

All ButtonElement definitions in a screen, which have no WebGUI equivalent for their programmed *action* (like "launching a new Java VM') are translated into an UNKNOWN action. The Frontend may show this e.g. as a disabled button with an "n/a" label.

- *par1:* The complete content of the message-id field in the original button definition.
- *par2:* null
- *par3:* null

8.5.37 ChartElement

The ChartElement shows a strip chart of a numeric parameter. The chart element keeps a local history of the received values, advances with a constant speed of 1 pixel / second. The default y-scale is 1/division but may be changed by clicking to the chart with the right mouse button.

By default, the strip chart element lets the y-scale offset follow the displayed value that the recent measurement samples are shown in the diagram. This behavior is optimized for

applications where the strip chart shall indicate a 'trend' for the displayed value, using an element height of only 50 pixels or less.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ChartElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to. This should point to a numeric parameter to make sense.
label	String	The label shown above the strip chart
font	String	The font to be used for the label
color	String	The color used for the label and the strip chart line.
mode	String	The strip chart's display mode. This mainly controls the scaling behavior of the chart. See Display Modes below.
scale	double	The scale 1/div
minValue	double	The value corresponding the bottom line of the widget
maxValue	double	The value corresponding the top line of the widget
minThreshold	double	Values below this threshold cause the widget to display a fault
maxThreshold	double	Values above this threshold cause the widget to display a fault

Display Modes

The ChartElement uses different display and scaling modes, depending on the display mode defined in *mode*. The table below lists the defined display modes an their behavior.

mode	**Description**

mode	Description
FLOATING-AUTO	Does a full autoscale. The y-offset of the strip chart is set that the newest value displayed appers at the middle of the y axis. The chart y-scale is evaluated in a 1-2-5 raster to the finest scale that allows all points in the history to be displayed in the chart area. All scaling parameters are ignored.
FLOATING-FIXED	Evaluates the y-offset like in **FLOATING-AUTO**, but applies a fixed y-scale as defined in *scale*. The *scale* value is 1/div and chart height is assumed as 2 divisions. So, the top line of the chart corresponds to y-offset + *scale*, the bottom line to y-offset -*scale*.
FIXED	Sets a fixed y-range from the *minValue* / *maxValue* parameters.
FIXED-THRESHOLD	Like **FIXED**, but also checks every new value against the *minThreshold* / *maxThreshold* limits. If outside the limits, the chart background turns to red.
ANTENNA-AZEL	Makes the element to be a AZ/EL x/y diagram instead of the strip chart. The details about this element type will be defined in a later version of the API.

8.5.38 AzElElement

The AzElElement shows the tracking histoy of an antenna controller as a cloud of points in a elevation over azimuth coorsinate system. Actually only SatService antenna conrollers provide the tracking history data for this screen element.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "AzElElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The device name (prepended by the M&C name) of the antenna controller for which the AzElElement shall be shown.
label	String	The label shown above the chart
font	String	The font to be used for the label

8.5.39 DeviceElement

The DeviceElement represents a device in the M&C user interface. It displays the status of the device by it's color/shape and gives access to the device window for this particular device by a double mouse click. The right mouse button launches a context menu with common operations for the device.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "DeviceElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The device ID this element represents in the UI. The device ID consists of the M&C name followed by a dot and the device name.
privilege	Number	The privilege level required to show details about the device and to change the device's operating state.
icon	String	The (base-) name of the icon to show for the device. See Icon Selection below.
showName	Boolean	true = show the device name als a label on top of the icon
showIsBackup	Boolean	true = use a different icon variant for this device if it is in 'is backup' state.
signalBackupId	String	A message ID to listen for a parameter from which the 'is backup' state is derived. Ignored unless *showIsBackup* is true.
backupValue	String	The parameter value which must be matched for the 'is backup' state.
font	String	The font to be used for the label.
color	String	The color to be used for the label (#RRGGBB)

Based on the *id* parameter, the DeviceElement subscribes for a number of parameters, the message IDs of these are as shown below:

{id}.fault: The device's summary fault state. May be one of**OK.**, **WARNING** or **Summary**

FAULT

{id}.faults.99: (Boolean) The device's communication fault

{id}.mode: The operation mode of the device. This is one of **OPERATIONAL**, **FAULT-SUPPRESSED**, **OUT-OF-SERVICE** and **MAINTENANCE**

{id}.info.signal.on: If the value reported via this messageID is **true** or **ON**, the device is considered to be actually ON-AIR. In this case, there is an additional emblem displayed at the upper right corner of the icon signalling this state.

signalBackupId: If the value reported via this messageID equals the *backupValue*, the DeviceElement considers the device to be a backup for something else.

Icon Selection

The DeviceElement shows the state of the device by switching between several variants of of the icon. The data model defines the base version of the icon which is shown when the device is in operating state without a fault. Other states are displayed by changing the icon to a variant which has a status code appended to the base name of the icon:

Icon Name	State	Example
basename.gif	Operational and OK	
basename-**C**.gif	There is no communication to the device	
basename-**F**.gif	The device shows a FAULT	
basename-**W**.gif	The device shows a WARNING	
basename-**S**.gif	The device id in fault suppressed mode	
basename-**M**.gif	The device is in maintenance mode	
basename-**O**.gif	The device is out of service	
basename-**B**.gif	The device is OK and used as backup	

In the sat-nms software there exist several sets of these icons, the is extensible by the customer. Supported image formats / file extensions are *.gif, *.jpg and *.png.

The pseudo code sniplet below describes how the DeviceElements is expected to combine the individual status variables to the name of icon to be shown.

```
if summary-alarm
    if communication-alarm
        use -C icon
    else
        use -F icon
else if summary-warning
    use -W icon
else if mode == MAINTENANCE
    use -M icon
else if mode == OUT-OF-SERVICE
    use -O icon
else if mode == FAULT-SUPPRESSED
    use -S icon
else if is-backup
    use -B icon
else
    use standard icon
```

8.5.40 DisplayElement

The DisplayElement is used to display M&C parameters read-only. It looks much alike the ParameterElement element, but never allows to change the parameter it displays.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "DisplayElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to
label	String	A label shown above the field / drop down
enableId	String	The enable ID (may be empty)

Key	Type	Value
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
drawFrameless	Boolean	true = display without a frame and with transparent background
variableBackgroundColor	Boolean	true = use a variable background color.
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

Remarks

Conditionally Enable: If the *enableId* property is not empty, the ParameterElement subscribes for this additional parameter and disables (disabled means "dimmed" in this case) the widget unless the received parameter value matches the values stated in *enableValue*.

Font Selection: The sat-nms software defines 6 preset fonts named 'small', 'plain', 'bold', 'title', 'huge' and 'typewriter'. The *font* property contains one of these names. The selected font is used for the text in the widget, the label above the entry field always is shown with the 'plain' font, unless *font* reads 'small', in this case the label is shown with the 'small' font as well. For information about fonts and font sizes see section Fonts in the appendix of this document.

Variable Background Color: With the *variableBackgroundColor* parameter set 'true', the DisplayElement listens to the additional parameter stated in *colorId* and sets the background color of the widget according to the value received. The received value is translated to a color (and optional 'bold' printing) through the *colors* array. If the received value does not match any of the values listed in the array, the first entry in the array is used as a default / fallback.

8.5.41 EditButtonElement

The EditButtonElement places an EDIT button to the screen. It appears as a simple button with the label "EDIT" on it. A screen definition containing an EDIT button switches the screen to Edit/Take mode. This means, parameter changes are not sent immediately to the server, but the screen remembers (and marks) all changes until the operator either clicks TAKE to send all changes to the server or clicks EDIT again to revert all changes made. Also see the definition of TakeButtonElement

Data Model (extends ScreenElement)

Key	Type	Value

Key	Type	Value
type	String	Always "EditButtonElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
privilege	Number	The privilege level required to switch to EDIT mode.

8.5.42 FaultElement

The FaultElement shows a fault flag. The faults page of the predefined device windows makes use of this display element.

The software treats device faults in a special way. In the variable list of a device driver the fault flags appear as variables called "faults.00" .. "faults.99". The software automatically produces a variable "config.faults.XX" for each fault flag "faults.XX" the driver defines. This configuration variable controls the priority of the fault.

Actually, FaultElement is not included in the API. If the original screen definition contains instances of this type, they are skipped and not included in the ScreenDefinition reported to the UI.

8.5.43 FrameElement

The FrameElement draws a sunken 3D frame, which is intended to be used to group other elements. The 3D frame's inside area is assumes to be transparent, it does not conceal the screen elements it encloses.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "FrameElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement

8.5.44 GaugeElement

The GaugeElement shows a numeric parameter value as a horizontal bar in an entry field like frame. The gauge element is capable to adjust the scale factor for the gauge automatically from the parameter's range definition. Alternatively the scale parameters may set explicitely.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "GaugeElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to. This should point to a numeric parameter to make sense.
label	String	The label shown above the strip chart
font	String	The font to be used for the label
color	String	The bar color. If thresholds are defined, this color is used while the value is inside the thresholds.
useMinMax	Boolean	If true, the min/max values for the gauge are defined in *minValue*, maxValue_. If false, the GaugeElement takes the limits from the watches parameter's range definition.
minValue	double	The value corresponding the left edge of the widget
maxValue	double	The value corresponding the right edge of the widget
useThresholds	Boolean	If true, the GaugeElement checks the value against the thresholds defined in *minThreshold*, *maxThreshold* and changes the color of the bar to *belowColor* or *above_Color* accordingly.
minThreshold	double	Values below this threshold cause the widget to display a fault
maxThreshold	double	Values above this threshold cause the widget to display a fault
belowColor	String	The bar color to be used if *useThresholds* is true and the actual value is below *minThreshold*
aboveColor	String	The bar color to be used if *useThresholds* is true and the actual value is above *maxThreshold*

Key	Type	Value
tickMode	String	One of 'NONE', 'TICKS', 'TICKS-LABELS'. 'TICKS' makes the element show ticks below the bar graph to indicate the bar position for the *minValue*, *minThreshold*, *maxThreshold* and *maxValue* values. The ticks are to be drawn outside the rectangle defining the element bounds. 'TICKS-LABELS' adds labels below the tick marks, showing the numeric values of the four limit parameters. The number of precision digits shown is taken from the subscribed value's range definition.

Restrictions for colors with *useThresholds* ###

Actually the colors to be used with *useThresholds* set are not freely definable. This is a restriction of how the sat-nms M&C software stores the screen definition, it uses a fixed set of color combinations when thresholds are enabled. These are the valid combinations:

belowColor	***color***	***aboveColor***	**sat-nms mode**
#ff0000	#00ff00	#ff0000	red - green - red
#ff0000	#ffff00	#00ff00	red - yellow - green
#00ff00	#ffff00	#ff0000	green - yellow - red

Using other color combinations than those from the table above will cause unpredictable results.

Special Behavior With Level-Adjust/Level-Control Devices

Normally the GaugeElement expects a numeric value to display in the bar graph. When used with the 'gauge' or the 'gauge2' parameter of the Level-Adjust/Level-Control devices, the GaugeElement must implement a special behavior:

The gauge/gauge2 parameters contain a comma separated string with a list of numeric and textual values. The GaugeElement must parse this string and update its display from the values parsed. The content of the gauge/gauge2 comma separated list is defined as follows:

Pos.	Name	Remark
0	val	The gauge value (numeric)
1	minLabel	The label to be shown for the min value below the graph (textual). Overwrites the label derived from the *minValue* field described above.

Pos.	Name	Remark
2	min	The value corresponding the left edge of the widget (numeric). Overwrites the value defined in the *minValue* field described above.
3	maxLabel	The label to be shown for the max value below the graph (textual). Overwrites the label derived from the *maxValue* field described above.
4	max	The value corresponding the right edge of the widget (numeric). Overwrites the value defined in the *maxValue* field described above.
5	minTLabel	The label to be shown for the minThreshold value below the graph (textual). Overwrites the label derived from the *minThreshold* field described above.
6	minThreshold	The value lower threshold value (numeric). Overwrites the value defined in the *minThreshold* field described above.
7	maxTLabel	The label to be shown for the maxThreshold value below the graph (textual). Overwrites the label derived from the *maxThreshold* field described above.
8	maxThreshold	The upper threshold value (numeric). Overwrites the value defined in the *maxThreshold* field described above.

In order to maintain compatibility to future level control devices, the GaugeElement should not use the parameter names or the driver type of the device to decide if this special behavior applies. Instead, the GaugeElement should make this decision from the data message it receives:

Contains the message a 9-element comma separated list?

If yes, the element should behave as with *useMinMax*=true and *useThresholds*=true, but with the settings contained in this list instead of the ones contained in the GaugeElement data.

Contains the message a 5-element comma separated list?

If yes, the element should behave as with *useMinMax*=true and *useThresholds*=false, but with the settings contained in this list instead of the ones contained in the GaugeElement data.

In all other cases the element should try to parse the message value to floating point value and display it with the settings given in the GaugeElement data object.

8.5.45 IconElement

The IconElement shows an arbitrary GIF/JPEG picture. If a message ID is defined with the

element properties, the image displayed will change with the parameter value addressed by the message identifier.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "IconElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	the message ID this element listens to
icon	String	the initial icon file name

When displayed the first time, the Iconelement shows the image specified in*icon*. If the message ID *id* is not empty, the IconElement dubscribes for this ID and changes the displayed icon every time a new value is received. To make use of this, the name of the icon should be structured in the following way:

```
base-name.{value-part}.{extension}
```

The value-part gets replaced by the parameter value received. For a boolean value for example, two icons 'red-lamp.false.png' and 'red-lamp.true.png'. The IconElement is configured to show 'red-lamp.false.png' initially. When the parameter addressed by *id* gets updated, the display changes according to the parameter value.

8.5.46 LatchingButtonElement

The LatchingButtonElement works much like the ParameterButtonElement described later in this document, but is specialized to show and control an enumeration parameter which knows exactly two states (e.g. on/off or true/false).

When the operator changes the state of the button by clicking it once, the latching button sends the 'other' parameter value to the device. On the other hand, if some other instance in the system changes the parameter state, the latching button recognizes this and changes the up/down state of the button accordingly.

Like the parameter button, the latching button may be labeled with text or an image. To reflect the actual state, the latching button always is configred with two text string or two image names which are shown according to the actual parameter value.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "LatchingButtonElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens for
privilege	Number	The privilege level required to change the button state / parameter value
labelUp	String	The label shown on the button when not pressed
labelDown	String	The label shown on the button when pressed
iconUp	String	The icon shown on the button when not pressed
iconDown	String	The icon shown on the button when pressed
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used for the button label
color	String	The color used for the label
mustQuery	Boolean	Show a query popup before changing the value
queryText	String	the text to show in the query
valueUp	String	The parameter value to send when the button is going up
valueDown	String	The parameter value to send when the button is going down
variableBackgroundColor	Boolean	true = use a variable background color
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

The LatchingButtonElement never uses a button label and an icon at the same time. Either *iconUp* / *iconDown* or *labelUp* / *labelDown* contain empty strings.

The *valueUp* and *valueDown* values are not only sent when the button is pressed or released. They also are used to set the button state when a parameter value is received though *id*: If the value matches *valueDown* the button goes to 'pressed' state, in all other cases the button gets released. Labels or icons change an this moment according to the new state.

8.5.47 LockButtonElement

The LockButtonElement defines a button to lock the operation of a number of device devices that no other user can change device settings. The button is in pressed state if at least one of the devices it is assigned to is locked by some user. An operator only may release the button if he set the lock by himself of if he has a privilege level of 150 or more.

Actually, LockButtonElement is not included in the API. If the original screen definition contains instances of this type, they are skipped and not included in the ScreenDefinition reported to the UI.

8.5.48 MCPElement

The MCPElement embeds the measurement display of a spectrum analyzer device in multi channel power measurement mode into the screen.

Actually, MCPElement is not included in the API. If the original screen definition contains instances of this type, they are skipped and not included in the ScreenDefinition reported to the UI.

8.5.49 ParameterButtonElement

The ParameterButtonElement is a button which sends a parameter value if pressed. A frequently used application for the parameter button is a RF-OFF button which sends a "tx.on=OFF" to a certain device. Beside this, a parameter button also may be programmed to play a parameter setting macro.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ParameterButtonElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element sends

Key	Type	Value
privilege	Number	The privilege level required to make a button click send a value
label	String	A label shown on the button
icon	String	An icon shown on the button
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
mustQuery	Boolean	true = show a query popup before changing the value
queryText	String	The text to show in the query. If empty, a default query text shall be used.
parameterValue	String	The parameter value to send
isMacroButton	Boolean	If true, this button starts a macro instead of sending a parameter
variableBackgroundColor	Boolean	true = use a variable background color
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

The ParameterButtonElement never uses a button label and an icon at the same time. Either *icon* or *label* is an empty string.

If no *parameterValue* is set, the ParameterButtonElement sends the button label or the icon name as the parameter value when clicked

Macro Buttons

The MacroButton is a special version of the ParameterButtonElement. A *isMacroButton = true* marks a ParameterButtonElement to be a MacroButton. In this case the 'id' field contains the name of the M&C where to play the macro and the macro name in this case, separated by a period. Example `VLC0001.myMacro`

Instead of calling 'poke' when the button is clicked, a POST /api/v1/playmacro/{mnc-name}/{macro-name} call must be made by the front end (Example

`POST /api/v1/playmacro/VLC0001/myMacro` .

8.5.50 ParameterElement

The ParameterElement is the common component to display and edit most types of M&C parameters. Depending on the data type of the parameter (the data type is detected automatically) the parameter elements appears as textual / numeric entry field, choice box or as display field for read only parameters.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ParameterElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to
privilege	Number	The privilege level requires to change this parameter
label	String	A label shown above the field / drop down
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
mustQuery	Boolean	true = show a query popup before changing the value
queryText	String	The text to show in the query. If empty, a default query text shall be used.
useSpinButtons	Boolean	true = use spin buttons for numeric values
spinSmallIncrement	String	Small spin increment, empty = use default
spinLargeIncrement	String	Large spin increment, empty = use default
useComboBox	Boolean	true = use a searchable combobox

Key	Type	Value

editableComboBox	Boolean	true = allow free text edit in the box
variableBackgroundColor	Boolean	true = use a variable background color.
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

Remarks

Widget Variants: Depending on the type of parameter and on the*height* parameter there are different widget types associated with the ParameterElement. As the parameter type is not known at the time the screen definition is read, the decision what widget type shall be used must be done after the parameter type description has been received from the server.

Parameter Type	***height < 40***	***height >= 40***
Text	single line entry field	multi line entry field, scrollable if text does not fit into the field
Numeric	single line entry field	single line entry field
Enum/Choice	drop down or combo box	scrollable list selection
r/o Text	single line display	multi line display, scrollable if text does not fit into the field
r/o Numeric	single line display	single line display
r/o Enum/Choice	single line display	single line display

Conditionally Enable: If the *enableId* property is not empty, the ParameterElement subscribes for this additional parameter and disables (disabled means "dimmed, not changeable") the widget unless the received parameter value matches the values stated in *enableValue*.

Font Selection: The sat-nms software defines 6 preset fonts named 'small', 'plain', 'bold', 'title', 'huge' and 'typewriter'. The *font* property contains one of these names. The selected font is used for the text in the widget, the label above the entry field always is shown with the 'plain' font, unless *font* reads 'small', in this case the label is shown with the 'small' font as well. For information about fonts and font sizes see section Fonts in the appendix of this document.

Operator Query: If the property *mustQuery* reads 'true', the ParameterElement pops up a 'Do you really want...' dialog before a parameter change is sent to the server. *queryText* contains the question to be shown in this case. In the question text, placeholders may used for two values: Any occurrences of the pattern **$P** get replaced by the parameter name (message ID). Any occurrences of the pattern **$V** get replaced by the new value to set. If*queryText* is empty, the ParameterElement uses a standard text instead.

Spin Buttons: With *useSpinButtons* set 'true', the ParameterElement shows spin buttons with editable numberic values. The spin buttons allow to increment/decrement the value by clicking on them. By default, a spin button click increments or decrements the lowest significant digit shown in the entry field. With the shift key hold down, the effective increment is x10. The above applies if the *spinSmallIncrement* / *spinLargeIncrement* properties are empty. If set, these values override the defaults.

ComboBox Variants: For CHOICE parameter the ParameterElement normally uses a simple drop down box. With selection parameter with a handful of choices this easy to operate. There are however situations where the ParameterElement must handle hundreds of choices (e.g. in satellite channel lists). For this the ParameterElement provides variants of the simple drop down box.

With the *useComboBox* parameter set 'true', the ParameterElement uses a special combo box, which implements some filtering on the displayed choices. The operator may enter some text into the edit field of the combo box and only choices which (partially) contain the the entered text are offered for selection.

With the *editableComboBox* parameter set 'true', the ParameterElement permits to send any entered text as the new parameter value to the server, not only one of the valid choices for this parameter.

Variable Background Color: With the *variableBackgroundColor* parameter set 'true', the ParameterElement listens to the additional parameter stated in *colorId* and sets the background color of the widget according to the value received. The received value is translated to a color (and optional 'bold' printing) through the *colors* array. If the received value does not match any of the values listed in the array, the first entry in the array is used as a default / fallback.

8.5.51 RadioButtonElement

The RadioButtonElement is a component to display and edit CHOICE type M&C parameters as a number of radio buttons. Depending on the height of the element, radio buttons are positioned in a row or in a column (*height*<=40 means position horizontally). The radio buttons are labeled with the choices of the parameter, there are as many radio buttons as choices in the parameter range.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "RadioButtonElement".

Key	Type	Value
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to
privilege	Number	The privilege level requires to change this parameter
label	String	A label shown above the field / drop down
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
mustQuery	Boolean	true = show a query popup before changing the value
queryText	String	The text to show in the query. If empty, a default query text shall be used.
drawFrame	Boolean	true = draw a gray rectangle around the radio button group.
variableBackgroundColor	Boolean	true = use a variable background color.
colorId	String	The message ID to listen for the background color
colors	Array	of ColorDefinition objects. Defines how to translate values of the *colorId* parameter to color values.

8.5.52 RectElement

The RectElement draws a rectangle with a selectable color. The element may listen to a parameter value and change the color of the rectangle according to the parameter value.

Data Model (extends ScreenElement)

Key	Type	Value

Key	Type	Value
type	String	Always "RectElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to. Is only relevant if *variableLineColor* reads *true*.
fill	Boolean	true = draw the rectangle filled, not only the outline.
color	String	The color used for the rectangle.
variableLineColor	Boolean	true = set the line/fill color from the value received from the parameter addressed by *id*.
useColorTranslation	Boolean	use the colors[] translation
colors	Array	of ColorDefinition objects. Defines how to translate values of the *id* parameter to color values if *useColorTranslation* reads *true*.

Variable Line Color

With *variableLineColor=true* the RectElement will change its line/fill color depending on the value of the parameter addressed by *id*. This way the rectangle can be used as a status indicator. The way the RectElement interprets the parameter value depends on the value of *useColorTranslation*.

If *useColorTranslation=false*, the RectElement tries to decode the line color directly from the parameter value. First it does the following tests on the parameter value (not case sensitive):

Parameter Value	Line Color And Thickness
ends with **BOLD**	The line is drawn thicker than normal
starts with **BLACK**	The line is drawn with this color
starts with **WHITE**	The line is drawn with this color

Parameter Value	Line Color And Thickness
starts with **RED**	The line is drawn with this color
starts with **BLUE**	The line is drawn with this color
starts with **GREEN**	The line is drawn with this color
starts with **YELLOW**	The line is drawn with this color
starts with **GRAY**	The line is drawn with this color
contains **TRUE**	If the message ID identifies the parameter as an alarm flag (the ID contains 'fault'), the line is drawn **RED-BOLD**, for other parameters it is drawn **GREEN-BOLD**
contains **FAULT**	The line is drawn **RED-BOLD**
starts with **ON**	The line is drawn **GREEN-BOLD**

If none of the above conditions apply, the RectElement tries to interpret the parameter value as a hex coded color (#RRGGBB). If this also fails, the standard line/fill color defined in *color* is used.

If *useColorTranslation=true*, the RectElement uses the ColorDefinition table in *colors[]* to decode the line's color and thickness.

8.5.53 SpectrumElement

The SpectrumElement embeds the spectrum display of a spectrum analyzer device in the screen. Actually, only the CSM-Spectrum-Analyzer device may be used with the SpectrumElement.

The SpectrumElement subscribes for a variety of parameter of the spectrum analyzer device to display its settings in the diagram area. It also permits to command some aspects of the spectrum analyzer device like the marker position. The spectrum data itself is read by subscribing for the 'trace' parameter of the device. This returns the spectrum data as a SpectrumTrace with each sweep of the spectrum analyzer. A complete description of the function of the spectrum element is given in a separate document.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "SpectrumElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The device name of the spectrum analyzer which shall be shown.
privilege	Number	The privilege level requires to change settings of the spectrum analyzer.
label	String	A label shown above the element
font	String	The font to be used for the label
color	String	The color used for the label (#RRGGBB)

8.5.54 SwitchElement

The SwitchElement is a special version of the device element which may be used to visualize the position of a switch in a user interface screen designed as a block diagram. The switch icon has all capabilities of a plain device icon display element. The context menu shown with this right mouse button additionally contains an option to toggle the switch position.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "SwitchElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The device ID this element represents in the UI. The device ID consists of the M&C name followed by a dot and the device name.
privilege	Number	The privilege level required to show details about the device and to change the device's operating state.

Key	Type	Value
icon	String	The (base-) name of the icon to show
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field
touchScreenMode	Boolean	true = use a different click response, optimized for touch screen
font	String	The font to be used for the label
color	String	The color used for the label (#RRGGBB)
mustQuery	Boolean	true = show a query popup before changing the value
queryText	String	The text to show in the query

Based on the *id* parameter, the SwitchElement subscribes for a number of parameters, the message IDs of these are as shown below:

{id}.fault: The device's summary fault state. May be one of**OK.**, **WARNING** or **Summary FAULT**

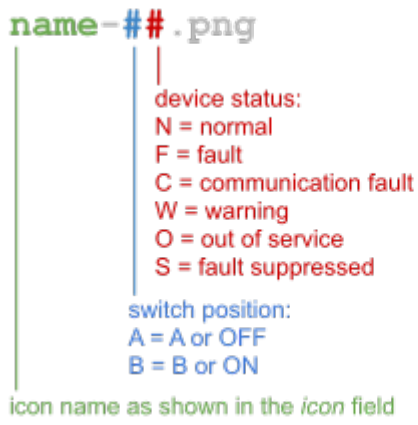
{id}.faults.99: (Boolean) The device's communication fault

{id}.mode: The operation mode of the device. This is one of**OPERATIONAL**, **FAULT-SUPPRESSED**, **OUT-OF-SERVICE** and **MAINTENANCE**

{id}.position: The switch position. May be either 'A' or 'B'. Recognized 'ON'/'OFF' es well and changes the the command sent with a switch toggle accordingly.

Icon Selection

The SwitchElement displays one icon of a given set depending on the switch position and the state of the switch device. For this the SwitchElement appends a '-' character, a 2-character status code and the suffix '.png' to the icon name given in *icon* in order to ge the file name to load / display:



8.5.55 TakeButtonElement

The TakeButtonElement places an TAKE button to the screen. It appears as a simple button with the label "TAKE" on it. The TAKE button complements the EDIT button described above in this document. It sends the changed parameter values to their destination when pressed.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "TakeButtonElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement

8.5.56 TargetListElement

The TargetListElement embeds the list of targets of a SatService-ACU-ODM antenna controller in the screen. Targets may be recalled (which moves the antenna to the stored position and sets the tracking parameters associated with this target), saved or deleted.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "TargetListElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement

Key	Type	Value
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The device name of the SatService-ACU-ODM. In device screens the *id* has to be interpreted differently, see below.
privilege	Number	The privilege level required to show details about the device and to change the device's operating state.
enableId	String	The enable ID (may be empty)
enableValue	String	The value which must be matched to enable the field

Device Name Indirection

The *id* parameter is interpreted differently depending on the context where the ODM Target List screen element resides:

- When placed in a user defined screen or in the main screen of the application, *id* is the name of the ODM device it shall refer to.
- When placed in the device screen of another device which defines a configuration variable with the antenna controller's device name, *id* is the name of this configuration variable and the name of the ODM device is derived from the content of this variable.
- Finally, when used in the device screen of the ODM device itself, *id* is '@'.

Target List Parsing

The target list element gets its information from a parameter 'target.list' the ODM device provides for this purpose. This variable contains the target list as a one line string with the target definitions appearing at fixed character positions.

Each target definition contains the target name and the azimuth / elevation / polarization angles. The target number is defined implicitly from the position of the target in the complete string. The format of each target definition is as follows:

```
target name (azimuth/elevation/polarization)
```

This string is padded with spaces to 45 characters length. With target numbers starting at 0, you can access a particular target in the string at position *n*45* with a length of 45 characters.

8.5.57 TextElement

The TextElement shows a label (a one line text string) with a chosable font / color.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "TextElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
label	String	The text to be drawn
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)

8.5.58 ThumbnailElement

The ThumbnailElement displays a thumbnail of the video actually processed by a device like an encoder, decoder or gateway. The displayed icon is a static image, fetched directly from the device and updated every couple of seconds.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "ThumbnailElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
id	String	The message ID this element listens to

REMARKS

The Thumbnail Icon element itself must fetch the image to display in regular intervals directly from the device. As a consequence of this the following restrictions apply:

- The device to get the thumbnail images from must support this feature.
- The device to get the thumbnail images from must be accessible in the network from the client's point of view.

With *urlType = PLAIN*, the *imageUrl* is used without modification to fetch the image. The image received from the device must be scaled to fit the screen element size.

With *urlType = ADVANCED* the front end appends some parameters to the URL as shown in the example below. In this case no scaling is done as the software queries the image already in the correct size from the device.

```
http://1.2.3.4/somepath?t=1693050862003&w=320&h=180
```

The example above starts from a *imageUrl = http://1.2.3.4/somepath* definition. With *urlType = ADVANCED* the front end must add the parameters *t*, *w*, and *h* as shown. The value of *t* is the actual time in milliseconds since Jan 1st 1970, 00:00 UTC, *w* and *h* define the dimension of the image in pixels. They usually math the *width* and *height* fields of the data model.

8.5.59 XYChartElement

This element shows the relation of two numeric variables in an X/Y diagram, featuring a 'trace' which shows the recent history of the values with a configurable depth. The update rate, the diagram scaling and much more is configurable with this screen element.

Data Model (extends ScreenElement)

Key	Type	Value
type	String	Always "TextElement".
xpos	Number	see ScreenElement
ypos	Number	see ScreenElement
width	Number	see ScreenElement
height	Number	see ScreenElement
idx	String	The message ID of the parameter to show at the x-axis
idy	String	The message ID of the parameter to show at the y-axis
label	String	The label to be drawn above the diagram
font	String	The font to be used
color	String	The color used for the label (#RRGGBB)
divisions	Number	The number of divisions shown in the diagram for both directions. Typical values are 2 ('hair cross'), 4 or 10.
interval	Number	The update time interval for the display in seconds. 0.1 means to add every 100msec a new value to the display and remove the oldest value from the buffer at the same time.

Key	Type	Value
bufsize	Number	The display maintains a "first in first out" buffer of a size defined with this parameter. The buffer provides a short time memory the display shows as a trace of past values. Typical values are in the range 100-300.
xorigin	Number	The value to be shown at the center of the x axis
yorigin	Number	The value to be shown at the center of the y axis
xscale	Number	The x axis scale in 1/division
yscale	Number	The y axis scale in 1/division
limits	Boolean	If true, the display monitors the actual X/Y values to be within the limits defined below. The limit values are shown as a dark red rectangle. When the actual X/Y values exceed the limits, the diagram background becomes red.
minx	Number	The lower x limit to check. Only meaningful if *limits* is true.
maxx	Number	The upper x limit to check. Only meaningful if *limits* is true.
miny	Number	The lower y limit to check. Only meaningful if *limits* is true.
maxy	Number	The upper y limit to check. Only meaningful if *limits* is true.

8.5.60 ColorDefinition

A ColorDefinition data object defines an entry of a value to color translation table which appears as the *colors* array with several ScreenElement definitions.

Data Model

Key	Type	Value
value	String	The parameter value for which the color shall be used
color	String	The color value (#RRGGBB)
bold	Boolean	true draws the text bold if the value matches

8.5.61 ItemList

The ItemList data object is used by the API at several places to return a list of named items to the front end, e.g. when a list of existing macros or device presets is required.

Data Model

Key	Type	Value
items	Array of String	The item list

8.5.62 Macro

A Macro data object contains a macro of the M&C software, a multi-line text in the sat-nms macro language containing settings / commands to be executed.

Data Model

Key	Type	Value
name	String	The name of this macro
macro	String	The macro itself (multi-line text, lines separated by '\n' character sequences).

8.5.63 PresetValue

Contains one parameter / value definition in a DevicePreset.

Key	Type	Value
name	String	The name of the driver variable this refers to. The driver variable name is the message ID of a parameter with the M&C name and the device name stripped off.
value	String	The value to be assigned to *varName* when the preset get applied to a device.

Values appear in the same way here as in the device preset file. This is formatted along the Range definition for this driver variable:

- FLOAT parameters are formatted with the precision defined in the range, but without a trailing unit string.
- INTEGER parameters appear as simple integer values, also without unit string.
- HEX parameters appear as hexadecimal values without unit string, letters A-F are upper case.
- BOOLEAN parameters are written as TRUE/FALSE.
- CHOICE parameters show the selected choice string.
- TEXT parameters are written without quotes, this means trailing blancs are not stored (this is a general limitation of the sat-nms M&C software)

8.5.64 DevicePreset

A DevicePreset data object contains a device preset of the M&C software.

Data Model

Key	Type	Value
name	String	The name of this preset
driver	String	The name of the device driver this preset is intended to be used with.
comment	String	The comment line appearing as the first line of a device preset file in the sat-nms M&C. Does not include the leading comment character ('#') appearing in the sat-nms preset file.
preset	Array of PresetValue	The value definitions from the device preset and an array of PresetValue definitions.

8.5.65 PresetVars

A PresetVars data object contains a description of an M&C device driver with its preset-storable variable definitions.

Data Model

Key	Type	Value
driver	String	The name of the device driver.
comment	String	The content of the COMMENT statement in the driver (includes the driver version).
vars	Array of Range	The Range definitions of all driver variable which may be stored in a preset. This includes all writable variables which have neither the SETUP nor the NOPRESET property set. The list contains a Range object for each variable with the data type, limits, choices, unit and precision as defined in the device driver file. The *messageId* field of each Range object contains the local name of the variable, not a fully qualified message ID

8.5.66 DeviceVars

A DeviceVars data object contains a description of an M&C device driver with all its variable definitions.

Data Model

Key	Type	Value
driver	String	The name of the device driver.

Key	Type	Value
comment	String	The content of the COMMENT statement in the driver (includes the driver version).
vars	Array of Range	The Range definitions of all driver variables. The list contains a Range object for each variable with the data type, limits, choices, unit and precision as defined in the device driver file. The *messageId* field of each Range object contains the local name of the variable, not a fully qualified message ID

8.5.67 KeyValPair

A KeyValPair defines a key / value pair as used with the Dictionary data model.

Data Model

Key	Type	Value
key	String	The name of the key
val	String	The value assigned to *key*

8.5.68 Dictionary

The Dictionary data model contains a list of key / value pairs.

Data Model

Key	Type	Value
dict	Array	An array of KeyValPair data objects

8.5.69 SatDbSatellite

The SatDbSatellite data record contains the basic properties for one satellite in the *satellites* database table. The fields in the SatDbSatellite data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

Data Model

Key	Type	Value
satelliteId	Number	unique, primary key, auto generated

Key	Type	Value
name	String	free text, typically the name as given by satellite operator
operatorId	Number	relation to table *satellite-operators*
noradNumber	Number	unique name (world wide standardized), also relation to table *norad_tle*
intDesignator	String	unique name (world wide standardized)
orbitPosition	Number	satellite orbit position in degrees
inclination	Number	satellite inclination in degrees
alias	String	free text, can be used by customer to add own name
modified	String	timestamp, generated by database at creation / modification time

8.5.70 SatDbBeaconAttenuation

The SatDbBeaconAttenuation data record contains the attenuation value stored in the database for one particular pair of antennaId and beaconId. This is the attenuation to be applied for the given beacon signal when receivbed by this antenn.

Data Model

Key	Type	Value
attenuationId	Number	unique, primary key, auto generated
beaconId	Number	ID of the beacon this data record belongs to
antennaId	Number	ID of the antenna this beacon belongs to
attenuation	Number	receiver attenuation, floating point, dB
modified	String	timestamp, generated by database at creation / modification time

8.5.71 SatDbBeacon

The SatDbBeacon data record contains the basic properties for one satellite in the *satellite_beacons* database table. The fields in the SatDbBeacon data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

There may be multiple beacon definitions assigned to one satellite. These beacons share the same *satelliteId*. One of these beacons is the default beacon, this and only this beacon has the

defaultBeacon flag set *true*.

Data Model

Key	Type	Value
beaconId	Number	unique, primary key, auto generated
satelliteId	Number	ID of the satellite this beacon belongs to
frequency	Number	beacon frequency, floating point, MHz
polarization	String	this is an enumeration, may be one of "H", "V", "RHCP" or "LHCP"
defaultBeacon	Boolean	true means "this is the default beacon for this satellite"
comment	String	free text describing the purpose of this beacon
modified	String	timestamp, generated by database at creation / modification time

8.5.72 SatDbTcAttenuation

The SatDbTcAttenuation data record contains the attenuation values stored in the database for one particular pair of antennaId and tcId. This is the attenuation to be applied for the given TC signal when transmitted by this antenna. The two attenuation values are applied to the same signal at different stages of the transmit chain, e.g. at the upconverter and the HPA.

Data Model

Key	Type	Value
attenuationId	Number	unique, primary key, auto generated
tcId	Number	ID of the TC signal this data record belongs to
antennaId	Number	ID of the antenna this beacon belongs to
attenuation1	Number	transmit attenuation1, floating point, dB
attenuation2	Number	transmit attenuation2, floating point, dB
modified	String	timestamp, generated by database at creation / modification time

8.5.73 SatDbTc

The SatDbTc data record contains the basic properties for one satellite in the*satellite_tc* database table. The fields in the SatDbTc data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how

relations between tables are maintained using IDs.

There may be multiple telecommand channel definitions assigned to one satellite. These channels share the same *satelliteId*. One of these channels is the default TC channel, this and only this channels has the *defaultTc* flag set *true*.

Data Model

Key	Type	Value
tcId	Number	unique, primary key, auto generated
satelliteId	Number	ID of the satellite this TC channel belongs to
frequency	Number	transmit frequency, floating point, MHz
polarization	String	this is an enumeration, may be one of "H", "V", "RHCP" or "LHCP"
defaultTc	Boolean	true means "this is the default TC channel for this satellite"
comment	String	free text describing the purpose of this channel
modified	String	timestamp, generated by database at creation / modification time

8.5.74 SatDbTmAttenuation

The SatDbTmAttenuation data record contains the attenuation values stored in the database for one particular pair of antennaId and tmId. These are the attenuation values to be applied for the given primary and secondary TM signals when received by this antenna.

Data Model

Key	Type	Value
attenuationId	Number	unique, primary key, auto generated
tmId	Number	ID of the TM signal this data record belongs to
antennaId	Number	ID of the antenna this beacon belongs to
attenuation1	Number	transmit attenuation1, floating point, dB
attenuation2	Number	transmit attenuation2, floating point, dB
modified	String	timestamp, generated by database at creation / modification time

8.5.75 SatDbTm

The SatDbTm data record contains the basic properties for one satellite in the*satellite_tm* database table. The fields in the SatDbBeacon data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

There may be multiple telemetry channel definitions assigned to one satellite. These channels share the same *satelliteId*. One of these TM channels is the default channel, this and only this channel has the *defaultTm* flag set *true*.

Data Model

Key	Type	Value
tmId	Number	unique, primary key, auto generated
satelliteId	Number	ID of the satellite this beacon belongs to
frequency1	Number	primary receive frequency, floating point, MHz
frequency2	Number	secondary receive frequency, floating point, MHz
polarization1	String	this is an enumeration, may be one of "H", "V", "RHCP" or "LHCP"
polarization2	String	this is an enumeration, may be one of "H", "V", "RHCP" or "LHCP"
defaultTm	Boolean	true means "this is the default telemetry channel for this satellite"
comment	String	free text describing the purpose of this beacon
modified	String	timestamp, generated by database at creation / modification time

8.5.76 SatDbSatOperator

The SatDbSatOperator data record contains the basic properties for one satellite in the *satellite_operators* database table. The fields in the SatDbSatOperator data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

There is a limited list of satellite operators, each being assigned to multiple satellites. The relation is made by the *operatorId* which is stored with each satellite.

Data Model

Key	Type	Value

Key	Type	Value
operatorId	Number	unique, primary key, auto generated
name	String	free text, company name of satellite operator
contact	String	free text, multiline, line breaks are coded as '\n' character sequences.
modified	String	timestamp, generated by database at creation / modification time

8.5.77 SatDbPosition

The SatDbPosition data record contains the antenna pointing information for one satellite and one antenna in the *satellite_positions* database table. The fields in the SatDbPosition data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

The *Satellite-Positions* table typically contains *number-of-satellites* x *number-of-antennas* records, as each satellite requires different antenna pointing angles for each particular antenna.

Data Model

Key	Type	Value
positionId	Number	unique, primary key, auto generated
satelliteId	Number	the ID of the satellite this SatDbPointing record refers to (relates to the *satellites* table).
azimuth	Number	antenna azimuth pointing angle in degrees (floting point)
elevation	Number	antenna elevation pointing angle in degrees (floting point)
polarization	Number	antenna polarization pointing angle in degrees (floting point)
satelliteColocation	Array of Number	contains the list of satellites (referenced by their satelliteId) which are seen at the same pointing angles by this particular antenna. See remark below
targetNumber	Number	a target number to be set at some antenna controllers (integer)
antennaId	Number	the ID of the antenna this SatDbPointing record refers to (relates to the *antennas* table).

Key	Type	Value
defaultPosition	Boolean	true means "this is the default position for this antenna"
comment	String	a free text describing the purpose of this database entry
modified	String	timestamp, generated by database at creation / modification time

Remark: Depending on the dish size of an antenna, the antenna "sees" not only the satellite it is pointed to but also other satellites which are at positions in the orbit very near to the first satellite. The *satelliteColocation* list contains the satelliteIds for these satellites.

Actually this list is not maintined by the the backend, the *satelliteColocation* will always read as an empty array.

8.5.78 SatDbAntenna

The SatDbAntenna data record describes one antenna in *antennas* database table. The fields in the SatDbPosition data record are 1:1 replicas of the SQL database record. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

Data Model

Key	Type	Value
antennaId	Number	the ID of the antenna this SatDbAntenna record refers to.
devicename	String	the name of the sat-nms device. controlling this antenna. The name has then name of the M&C system prepended, e.c. "VLC0001.ANTENNA-1"
alias	String	a free text describing the antenna.
modified	String	timestamp, generated by database at creation / modification time

8.5.79 SatDbTLEData

The SatDbTLEData data record contains the TLE ephemeris data for one satellite. The fields in the SatDbTLEData data record are 1:1 replicas of the SQL database record from the *norad_tle* table. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

Data Model

Key	Type	Value
noradNumber	Number	the norad number of the satellite this SatDbTLEData record refers to. As the norad number is unique, this field is used as the primary key in the database table.
tleName	String	the name of the satellite as stated in the original TLE parameter set.
tleLine1	String	the first line of TLE data
tleLine2	String	the second line of TLE data
modified	String	timestamp, generated by database at creation / modification time

Remark: The TLE (aka Nasa Two Line Elements) format identifies single parameters by their exact position in the lines 1/2. This requires that the *tleLine1* and *tleLine2* fields are processed exactly as they are, there must no whitespace be added or removed from the start or end of the value, multiple blanc characters must not be compressed to one. This is essential to keep the values readable.

8.5.80 SatDbI11Data

The SatDbI11Data data record contains the Intelsat 11 parameter ephemeris data for one satellite. The fields in the SatDbI11Data data record are 1:1 replicas of the SQL database record from the *intelsat_11parameters* table. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

Data Model

Key	Type	Value
i11Id	Number	a unique ID of this SatDbI11Data record (auto generated).
satelliteId	Number	the ID of the satellite this SatDbI11Data record refers to.
i11Name	String	the name of the satellite as stated in the original I11 parameter set.
i11Data	String	the 11 ephemeris parameters, floating point, separated by semicolon characters
defaultI11	Boolean	true means "this is the default I11 dataset for this satellite"
comment	String	free text describing the purpose of this dataset
modified	String	timestamp, generated by database at creation / modification time

8.5.81 SatDbTableTracking

The SatDbTableTracking data record contains the table tracking information for one satellite. The fields in the SatDbTableTracking data record are 1:1 replicas of the SQL database record from the *table_tracking* table. Please refer to the database model description at section Satellite Database how relations between tables are maintained using IDs.

Data Model

Key	Type	Value
ttId	Number	a unique ID of this SatDbTableTracking record (auto generated).
satelliteId	Number	the ID of the satellite this SatDbTableTracking record refers to.
antennaId	Number	the ID of the antenna this SatDbTableTracking record refers to.
filename	String	the name of the data file containing the position data of the satellite. Should be treated as a free text entry field in the UI.
defaultTt	Boolean	true means "this is the default table tracking dataset for this satellite"
comment	String	free text describing the purpose of this dataset
modified	String	timestamp, generated by database at creation / modification time

8.5.82 SatDbSatDetails

The SatDbSatDetails data record contains detailed information for one satellite. It is returned by a GET performed on the /api/v1/satdetails endpoint, collecting all information known about the satellite in one single document.

Data Model

Key	Type	Value
satellite	SatDbSatellite	the basic properties of the satellite
operator	SatDbSatOperator	the satellite operator assigned to this satellite
beacons	Array of SatDbBeacon	a list of all beacons defined for this satellite, may contain 0 or more elements.
tcChannels	Array of SatDbTc	a list of all telecommand channels defined for this satellite, may contain 0 or more elements.
tmChannels	Array of SatDbTm	a list of all telemetry channels defined for this satellite, may contain 0 or more elements.

Key	Type	Value
tleData	Array of SatDbTLEData	the TLE ephemeris data defined for this satellite, may contain 0 or 1 elements.
i11Data	Array of SatDbI11Data	the I11 ephemeris data defined for this satellite, may contain 0 or more elements.
tableData	Array of SatDbTableTracking	the table tracking information for this satellite, may contain 0 or more elements.

The SatDbSatDetails data record does not contain any antenna pointing information as this also depends on the antenna used to see this satellite.

8.5.83 SatDbTleImport

The SatDbTleUpload data record is used to upload a file containing a list of TLE definitions to the satellite database. It is used with the /api/v1/tleimport API endpoint.

Data Model

Key	Type	Value
fileName	String	the name of the file which is to be imported. This is used in the backend for logging etc.
replaceAll	Boolean	Controls the behavior of the import process, FALSE merges the database and file content together, overwiting data sets with the same norad number. TRUE ensures that after the import only the TLE datasets from imported file are in the database.
fileContent	String	The content of the file to be imported, BASE64 coded.

8.5.84 SatDbState

The SatDbState data record reports the state of the connection of the backend to the database server. The state may be queried by a GET /api/v1/dbstate API call.

Data Model

Key	Type	Value
connected	Boolean	true if the backend is connected to a DB server
primary	Boolean	true if the backend is connected to the primary DB server
serverAddress	String	the IP address of the DB server the backend is actually connected to

8.5.85 ChannelData

The ChannelData data record holds the information about one satellite channel stored in the satellite channel database. It is used by the /api/v1/satellites/##/channels API calls

Data Model

Key	Type	Value
channelId	Number	A unique ID of this ChannelData record (auto generated).
satelliteId	Number	The ID of the satellite this ChannelData record refers to.
name	String	The user defined channel name.
fullName	String	The full name of this channel as it appears as a selection in the user interface. The full name is built from the satellite's name, a '-' character and the *name* field in this record. The full name must be unique because the operator selects satellite channels by this name. With POST or PATCH calls to the channel database the backend ignores this field, it automatically generates the *fullName* from the satellite name and *name* .
user	String	The name of the user who lastly edited the channel
programTitle	String	Name of the program transmitted or received with this channel
comment	String	A one line comment describing this satellite channel
rxFrequency	Number	The receive frequency in MHz (3 digits precision)
rxPolarization	String	The receive polarization, one of 'X', 'Y', 'L' or 'R'
txFrequency	Number	The transmit frequency in MHz (3 digits precision)
txPolarization	String	The transmit polarization, one of 'X', 'Y', 'L' or 'R'
dvbMode	String	The DVB mode, one of 'AMCD', 'AMCDL', 'AMCDVBS', 'AMCNBC', 'AMDVBS', 'ATSC', 'AUTO', 'DSNG', 'DSS', 'DVBS', 'DVBS2', 'DVBS2X', 'DVBT', 'DVBT2', 'NS3', 'NS4' or 'TURBO'
nlcMode	String	The NLC mode, one of 'OFF' or 'ON'
symbolRate	Number	The symbol rate in Msym/sec (4 digits precision)

Key	Type	Value
fec	String	The FEC rate, one of 'AUTO', '1/1', '1/16', '1/2', '1/3', '1/32', '1/4', '1/5', '1/8', '2/2', '2/3', '2/5', '2/9', '3/16', '3/2', '3/3', '3/4', '3/5', '4/15', '4/2', '4/3', '4/5', '4/9', '5/16', '5/2', '5/6', '5/9', '6/2', '6/5', '6/7', '7/15', '7/2', '7/8', '7/9', '8/10', '8/15', '8/16', '8/2', '8/9', '9/10', '9/2', '9/20', '10/11', '10/2', '11/12', '11/15', '11/2', '11/20', '11/45', '12/2', '12/24', '13/14', '13/15', '13/18', '13/2', '13/24', '13/30', '13/45', '14/24', '14/45', '15/16', '15/25', '16/25', '17/30', '19/20', '19/30', '21/22', '21/44', '22/45', '23/36', '25/36', '26/45', '28/45', '29/45', '31/45', '32/45', '37/45', '41/5', '43/27', '44/27', '45/180', '45/28', '46/28', '47/26', '48/26', '50/15', '55/56', '60/180', '64/57', '70/140', '70/150', '72/180', '77/90', '80/100', '80/180', '90/180', '90/30', '100/180', '108/180', '114/180', '120/180', '126/112', '126/180', '135/180', '144/180', '150/180', '160/180', '162/180', '188/204', '194/178', '204/188', '208/192', '219/201', '225/205', '380/400', '442/485', '485/422', '510/511' or '510/512'
modulation	String	The modulation type, one of '128APSK', '128QAM', '16APSK', '16PSK', '16QAM', '16QUAM', '256APSK', '256QAM', '32APSK', '32QAM', '64APSK', '64QAM', '8APSK', '8PSK', '8QAM', 'AQPSK', 'AUTO', 'BPSK', 'OQPSK', 'PSK8', 'QAM', 'QAMAUTO', 'QPSK', 'SEQ', 'SOQPSK', 'SQPSK', 'UQPSK', 'VIT', 'VSB16' or 'VSB8'
rolloff	String	The roll off factor, one of '0.02', '0.05', '0.10', '0.15', '0.20', '0.25' or '0.35'
pilots	String	The pilots on/off switch, one of 'OFF' or 'ON'
bitRate	Number	The data rate in Mbit/sec (4 digits precision)
useRate	String	Selects the way the data rate is specified, one of 'SYMBOLRATE' or 'BITRATE'
packetSize	String	The packet size, one of '188' or '204'
frameSize	String	The frame size, one of 'SHORT' or 'NORMAL'
videoRate	Number	The video data rate in Mbit/sec (4 digits precision)
vrAuto	String	The video rate auto switch, one of 'FIXED' or 'AUTO'

Key	Type	Value
profile	String	The video encoding profile, one of 'MPEG2-MP@ML-420', 'MPEG2-MP@LL-420', 'MPEG2-HP@ML-422', 'MPEG2-HP@LL-422', 'MPEG2-SP@LL-420', 'MPEG2-SP@ML-420', 'MPEG2-MP@H14-420', 'MPEG2-MP@HL-420', 'MPEG2-HP@H14-422', 'MPEG2-HP@HL-422', 'MPEG2-HP@HL-420', 'MPEG2-HP@H14-420', 'MPEG2-HP@ML-420', 'MPEG4-BP@L2-420', 'MPEG4-BP@L3-420', 'MPEG4-BP@L4-420', 'MPEG4-MP@L3-420', 'MPEG4-MP@L4-420', 'MPEG4-MP@L4.2-420', 'MPEG4-HP@L3-420', 'MPEG4-HP@L4-420', 'MPEG4-HP@L4.2-420', 'MPEG4-HP@L3-422', 'MPEG4-HP@L4-422' or 'MPEG4-HP@L4.2-422'
eirp	Number	The transmit EIRP in dBW (2 digits precision)
redEirp	Number	The reduced EIRP for line up in dBW (2 digits precision)
autoLineup	String	Configures automatic line up, one of 'OFF' or 'ON'
audioRate1	String	Audio channel 1 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audioRate2	String	Audio channel 2 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audioRate3	String	Audio channel 3 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audioRate4	String	Audio channel 4 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audioChannels	Number	Number of audio channels, (integer, 1-4)
decoderInput	String	Decoder input, one of 'SAT', 'IP' or 'ASI'
ipType	String	IP adressing type, one of 'UNICAST' or 'MULTICAST'
ipProtocol	String	IP protocol, one of 'UDP', 'RTP', 'TCP' or 'ZIXI'
ipSourceAddress	String	Source IP address in dotted quad notation
ipSourcePort	Number	Source port number (integer, 0-65535)
ipDestinationAddress	String	Destination IP address in dotted quad notation

Key	Type	Value
ipDestinationPort	Number	Destination port number (integer, 0-65535)
ipFec	String	IP FEC selection, one of 'OFF' or 'ON'
ipBufferSize	Number	Buffer size (integer)
encoderPhysInterface	Number	Encoder physical output number (integer, 1-4)
decoderPhysInterface	Number	Decoder physical input number (integer, 1-4)
modified	String	timestamp, generated by database at creation / modification time

8.5.86 StreamKeyData

The StreamKeyData data record holds the information about one BISS or SRT key in the *streamkeys* table of the database . It is used by the /api/v1/streamkeys API calls.

Data Model

Key	Type	Value
keyId	Number	A unique ID of this StreamKeyData record (auto generated).
name	String	The user defined name of this stream key. This name also must be unique because the operator selects the key by this name.
keyType	String	The key type, one of 'BISS-1', 'BISS-E' or 'PASSPHRASE'.
key	String	The key value associated with the id and name in this record. For biss keys this is a string entirely consisting of the hexadeximal characters 0123456789ABCDEF, it is either 12 or 16 characters long. For other key types the key is free text.
modified	String	timestamp, generated by database at creation / modification time

8.5.87 TreeViewNode

The TreeViewNode data record holds the information about one node in the sat-nms tree view and the tree below this node. The complete tree is partially autogenerated and user defined, see below about the standard tree structure used in the sat-nms software.

Data Model

Key	Type	Value

Key	Type	Value
nodeName	String	The (displayed) name of this node. This may be a M&C name, a subsystem name, a device name or a screen name, depending on the type of this node. See below on details about node types and names.
nodeType	String	One of ROOT, MNCNODE, DEVICELIST, SUBSYSTEM or DEVICE. See below on details about node types and names.
children	Array	An array of other TreeViewNode objects being the children of this node. May be null, this denotes a leaf node.

Standard Tree Structure

The general structure of the tree view ist autogenerated by the software. User defined branches with subsystem definitions are integrated at certain points of the tree.

```
ROOT
  +-- MNC001
  +-- MNC002
     +-- Devices
     +-- SUBSYSTEM-1
     +-- SUBSYSTEM-2
        +-- SUBSUBSYSTEM-1
           +-- DEVICE-1
           +-- DEVICE-2
     +-- DEVICE-3
     +-- DEVICE-4
  +-- MNC003
```

A tree always consists of one ROOT node. The children of this node are the M&C systems managed by the backend (one MNCNODE for each M&C system). Each MNCNODE has at least one child, a DEVICELIST node containing the list of devices managed by this M&C. Up to here all nodes are auto-generated and not c hangeable by the user. Additionally, each MNCNODE may have zero or more SUBSYSTEM nodes with user defined groups of devices or nested subsystems.

Node Types and Names

A TreeViewNode may be one of the types ROOT, MNCNODE, DEVICELIST, SUBSYSTEM or DEVICE. The table below lists the properties of these node types in short form:

type	***auto-generated***	***may contain***	***name***
ROOT	yes	MNCNODE	always 'TreeView'

type	*auto-generated*	*may contain*	*name*
MNCNODE	yes	DEVICELIST, SUBSYSTEM	M&C name
DEVICELIST	yes	DEVICE	always 'Devices'
SUBSYSTEM	no	SUBSYSTEM, DEVICE	subsystem name
DEVICE	within a DEVICELIST	-/- (leaf node)	device name

The **ROOT** node is - as the name suggests - the root of the tree view tree. There is exactly one **ROOT** node in the tree, its children are one or more**MNCNODE** nodes, as many as M&C systems are configured to be managed by the backend. The displayed name of each **MNCNODE** node id the ID / name of this M&C, this is the same as used in message IDs. The list of **MNCNODE** nodes is auto-generated by the backend, derived from its configuration data.

The first child of each **MNCNODE** node always is a **DEVICELIST** node containing the complete list of devices configured on this M&C. This node also is automatically created by the backend, the device list is in 'natural' order, meaning that the devices appear in the same order as they do in the M&C configuration file / screen.

DEVICE nodes are the leaf nodes of the tree. The name of a**DEVICE** node is the name of the device without the name of the M&C it is contained in.

SUBSYSTEM nodes define a group of devices or nested subsystems. They are the only user defined node objects in the tree. The name of a **SUBSYSTEM** node is user defined, but as this name appears in the message ID of the summary fault state of a subsystem, the same restrictions applay for subsystem names as for device names. They may consist of upper case letters 'A' .. 'Z', digits and the '-' - character.

Subsystems

Subsystems defined by a **SUBSYSTEM** node in the tree are managed by the M&C like a virtual device which has a summary fault flag which reads as the maximum fault condition that appears at one of the elements the subsystem contains. The definition of all configured subsystems in a M&C is stored by the M&C itself, not by the backend. Due to the M&C-local architecture of subsystems the following rules apply to them:

The name of a subsystem consists of the same limited set of characters like device names do.

A subsystem may contain devices or other subsystems. These children must be located at the same M&C as their parent subsystem. Subsystems cannot be defined across multiple M&Cs.

Each subsystem distributes a summary fault variable which can be used to display the fault state of the subsystem. The full messgeId of this variable is

`{M&C-name}.SUBSYSTEM.{subsystem-name}.fault`

or for nested subsystems

`{M&C-name}.SUBSYSTEM.{subsystem-name}.{sub-subsystem-name}....fault`

These variables - like a .fault value of a device - read one of the strings "OK.", "WARNING" or "Summary FAULT".

8.5.88 DatabaseVersion

The DatabaseVersion reports the actual version (migration_step) of the database together with the version required by the backend and a fault flag indicating that the database version is too old for this backend.

Data Model

Key	Type	Value
reported	Number	The version / migration_step reported by the database. a value of -1 means 'undefined'
required	Number	The version / migration_step required by the backend
fault	Boolean	True of the database version is too old

8.5.89 DebugMessage

The DebugMessage data record is used for the communication with a M&C debug terminal. It transports the lines to be displayed in the terminal via the websocket and also the commands to be sent to the debug terminal using the /api/v1/debug API call the other way round.

Data Model

Key	Type	Value
msg	String	The line to be transferred (without any newline character at the end)
error	Boolean	True if this is an error message issued by the backend rather than a message from the M&C

8.5.90 RedundancyState

The RedundancyState data record carries the actual state of a particular M&C redundancy switching logic. It is returned by a GET /api/v1/redundancy API call.

Data Model

Key	Type	Value

Key	Type	Value
mncName	String	The name of the redundant M&C pair for which this data record reports the state
enabled	Boolean	Reports if this redundancy is enabled (true/false)
state	String	Reports the actual state of the redudancy switching logic, one of 'PRIMARY', 'BACKUP', 'NONE'

8.5.91 RedundancySummary

The RedundancySummary data record carries the actual state of the M&C redundancy switching logic for all redundant M&Cs. It is returned by a GET /api/v1/redundancy API call.

Data Model

Key	Type	Value
redundantMnCs	Array	An array of RedundancyState objects, reporting the states to all redundant M&Cs. The array may be empty if no redundant M&Cs are configured in the backend.

8.5.92 RedundancyCmd

The RedundancyCmd data record carries the command to be executed with a /api/v1/redundancy API call.

Data Model

Key	Type	Value
cmd	String	The command to be executed. Valid commands are: 'ENABLE' = enable redundancy switching in case of a communication fault. 'DISABLE' = disable redundancy switching. 'RESET' = switch back to the primary IP address for the M&C 'FORCE' = force a redundancy switch to the backup IP address for the M&C even if the communication at the primary IP address works fine.

8.5.93 RestartCmd

The RestartCmd data record carries the command to be executed with a/api/v1/restart API call.

Data Model

Key	Type	Value

Key	Type	Value
cmd	String	The command to be executed. The only valid command is "RESTART". The restart is only executed if *cmd* has this value.

8.5.94 ScheduleEvent

The ScheduleEvent data record carries the data of one event in the M&C macro scheduler.

Data Model

Key	Type	Value
eventId	Number	An integer value in the range 1 .. 2147483647 uniquely identifying this event in the schedule. A value of 0 means undefined.
groupId	Number	The event's group identifyer. this is the *eventId* if the master event in the group. Even this master event has its own *eventId* set as *groupId*, a *groupId* of 0 means this event is not grouped.
state	String	One of the following: DONE, UPCOMING or MISSED
repeatMode	String	One of the following: NONE, DAILY, WEEKLY or MONTHLY
enabled	Boolean	*true* enables the execution of the event's macro, *false* inhibits this.
description	String	A description for this event given by the operator.
firstExecution	String	The time of the first execution of the event.
nextExecution	String	The time of the next execution of the event.
lastExecution	String	The date of the last execution of the event if a repeat mode is set. For non-repeating events this reads null. The time stamp should contain a time (e.g. 00:00:00) although the scheduler ignores this time.
macro	String	The macro to be executed. newline characters on the macro thave to written as the character sequence "\n".
dict	Array	An optional array of KeyValPair definitions which may be used to append additional information to the event.

Remarks

- New events shall use the lowest *eventId* above 1000 which is not used in the schedule.
- All time stamps are formatted as 'YYYY-MM-DDTHH:MM:SSZ' ans expressed in UTC.

- In the macro text newline characters are expressed as a "\n" character sequence.
- The fields *groupId* and *dict* are not used by the macro scheduler appliaction. The Web GUI shall not show these fields snd shall not present them for editing.

8.5.95 Schedule

The Schedule data record carries the complete shedule of an M&C macro scheduler. It is used with the /api/v1/schedule API call.

Data Model

Key	Type	Value
events	Array	An array of ScheduleEvent data objects defining the complete schedule.

8.5.96 DeviceDefinition

The DeviceDefinition data record carriers the information about one device in an M&C's device setup.

Key	Type	Value
name	String	The name of the device
driver	String	The device driver

8.5.97 DeviceThreadDefinition

The DeviceThreadDefinition data record carriers the information about one device thread in an M&C's device setup.

Key	Type	Value
port	String	The communication port / interface this thread uses
protocol	String	The protocol this thread uses
idle	Number	The idle time of this thread (msecs)
devices	Array	An array of DeviceDefinition objects containing the devices of this thread

8.5.98 DeviceSetup

The DeviceSetup data record carriers the complete information of an M&C's device setup.

Key	Type	Value
comment	String	A short one line description (e.g. time stamp an user name of the last change)
threads	Array	An array of DeviceThreadDefinition objects containing the device thread definitions of this setup

8.5.99 FRViewProperties

The FRViewProperties data record contains the setting stored for a file recorder viewer.

Key	Type	Value
title	String	The diagram title
traces	Array	An array of FRViewTraceDescription objects containing the trace names and unit strings. The File-Recorder device records four traces of data, so this array always contains four elements. When sent to the backend also four elements must be supplied.
presets	Array	An array of FRViewTracePreset objects containing the scaling presets defined for this file recorder view. This array always contains eight elements, when sent to the backend also eight elements must be supplied. In the Java-UI the presets are identified by position in this array, so the front end should not re-order them.

8.5.100 FRViewTraceDescription

The FRViewTraceDescription data record contains a basic description (label, unit) for one trace within the FRViewProperties data record.

Key	Type	Value
unit	String	The unit string to be displayed at the axis for this trace
name	String	The name of the trace

8.5.101 FRViewPreset

The FRViewPreset data record contains the data stored for one user preset within the FRViewProperties data record. This includes the diagram scaling and some additional information like trace colors etc.

Key	Type	Value

Key	Type	Value
absstart	String	The (absolute) starttime of the diagram, expressed as an ISO 8601 string, example: `2021-03-26T08:02:30Z` , time zone is always UTC.
relstart	Number	The starttime of the diagram, in seconds relative to the newest data record recorded.
tscale	String	The time axis scaling, one of ("15s", "30s", "1m", "3m", "5m", "10m", "30m", "1h", "3h", "6h", "12h", "1d", "2d", "6d", "30d"). The values are per division of the time axis
traces	Array	An array of FRViewTraceScaling objects, each describing the scaling properties for one diagram trace. The backend will always report four traces, even if not all four traces are configured in the File-Recorder device. When sent to the backend, each preset **must** provide four elements in this array to be recognized properly.
name	String	The (optional) name of the preset

8.5.102 FRViewTraceScaling

The FRViewTraceScaling data record contains the scaling information for one diagram trace within the FRViewPreset data record.

Key	Type	Value
yref	Number	The reference value (the value shown at the half diagram height)
yscale	Number	The Y-scale value (y-units / division with 10 divisions diagram height). The values must match a 1/2/5 stepping, they will be read back rounded to this if other values are supplied.
enabled	Boolean	TRUE means this trace shall be shown
color	String	The trace color, expressed as a hexadecimal RGB value preceeded by a '#' character

8.5.103 AcuTarget

The AcuTarget data model contains the basic properties (name, az, el, pol) for one target / satellite stored on an ACU device

Key	Type	Value
targetNo	Number	The target number on the ACU

Key	Type	Value
satelliteName	String	The name of the target
azimuth	Number	The stored azimuth angle
elevation	Number	The stored elevation angle
polarization	Number	The stored polarization angle

8.5.104 AcuTargetList

The AcuTargetList data model contains the target list read from an ACU device, showing all used target memories as an array of AcuTarget objects.

Key	Type	Value
acuName	String	Name of the ACU device
acuTargets	Array	Target list as an array of AcuTarget objects.

8.5.105 InventoryItem

The InventoryItem data record contains the data stored for one particular item in the inventory database. It is used to report, add or modify the properties of an inventory item thru the API. Beside this, the InventoryItem record is used to specify a filter when getting a list of InventoryItem records. in such a case, all fields which are missing or null are interpreted as a wildcard, specified fields must match to include the item in the list.

Key	Type	Value
itemId	Number	A unique ID of this record (auto generated).
serialNo	String	The serial number of the item / device
vendor	String	The vendor name (for serach filters)
model	String	The modem name (for serach filters)
state	String	The administrative state of the device
comment	String	free text
modified	TimeStamp	automatically created timestamp of last change

8.5.106 InventoryDevice

The InventoryDevice data record contains the device mappings for aInventoryItem. There may be multiple devices mapped to one item in the inventory database.

Key	Type	Value
deviceId	Number	A unique ID of this record (auto generated).
itemId	Number	The ID of the InventoryItem this record refers to
mncName	String	The serial number of the item / device
deviceName	String	The vendor name (for serach filters)
state	String	The administrative state of the device
online	Boolean	true means the device is present
modified	TimeStamp	automatically created timestamp of last change

8.5.107 InventoryLogEntry

The InventoryLogEntry data record contains the data of one entry in the inventory life cycle log. It is used to report, add or modify the properties of an inventory log entry the API. Beside this, the InventoryLogEntry record is used to specify a filter when getting a list of InventoryLogEntry records. in such a case, all fields which are missing or null are interpreted as a wildcard, specified fields must match to include the item in the list.

Key	Type	Value
entryId	Number	A unique ID of this record (auto generated).
itemId	Number	Links to the inventory_items entry this log entry refers to.
mncName	String	The M&C which issued this message or null if the message was entered at the UI
devName	String	The satnms device name which issued this message
message	String	the message text
created	TimeStamp	timestamp, generated by database at creation time

8.5.108 DocumentItem

The DocumentItem data record contains the data of one entry in the backend's document list. It is used to report, add or modify the properties of a stored document thru the API. Beside this, the InventoryLogEntry record is used to specify a filter when getting a list of DocumentItem records. in such a case, all fields which are missing or null are interpreted as a wildcard,

specified fields must match to include the item in the list.

Key	Type	Value
documentId	Number	A unique ID of this record (auto generated).
fileName	String	Name of the file. The name must be unique, all files are stored in the same directory.
contentType	String	Content type of the file. must be one of application/pdf, image/png or image/jpg.
fileContent	String	The file content as a BASE64 coded string
driver	String	The satnms driver name this document refers to or null if it does not refer to a driver / device type.
mncName	String	The M&C name this document refers to or null if it does not refer to a M&C.
comment	String	free text
modified	TimeStamp	automatically created timestamp of last change

8.5.109 DocumentList

The DocumentList data record contain a list of DocumentItem records.

Key	Type	Value
documents	Array	An array of DocumentItem records.

8.5.110 Thumbnail

The Thumbnail data record contains the data fro a thumbnail image when fetched using the /api/v1/thumbnail API call.

Key	Type	Value
messageId	String	The full message ID of the thumbnail image
image	String	The binary thumbnail image (jpf or png), base64 encoded.

8.5.111 BackendInfo

Key	Type	Value

Key	Type	Value
backendName	String	The current backend name
role	String	Role of current backend
isPrimary	Boolean	Whether the backend is main or not
backendNames	String []	Array of backend names (string) to set the activeBackend name

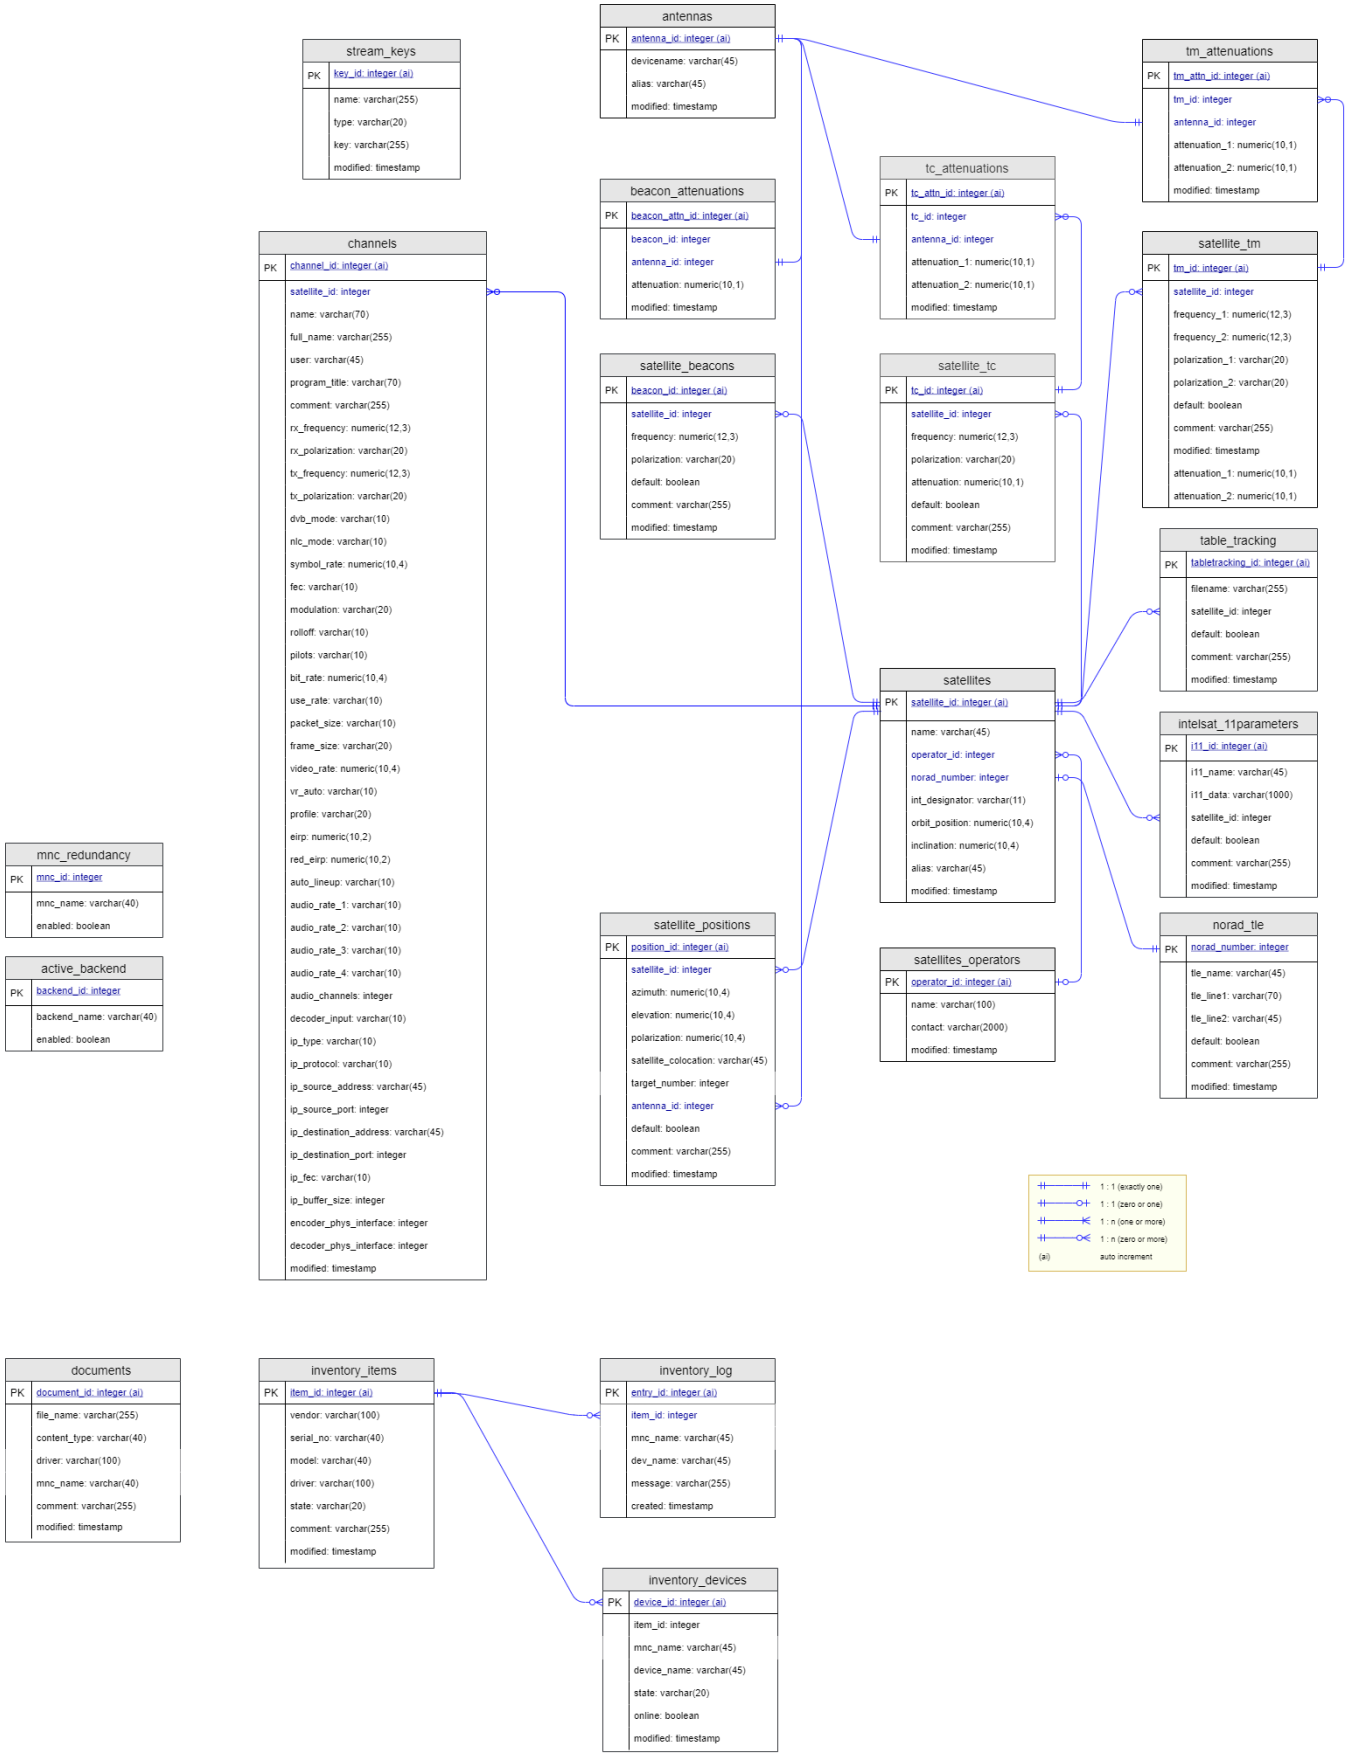
8.5.112 UISettings

The User-Settings data record contains changed settings by the user. Not saved or changed settings will be generated from Backend.

Key	Type	Value
settingsId	Integer	A Unique Id of an setting
key	String	Setting name
value	TEXT	The saved value of the setting
username	String	Username to which the setting belongs
isLocked	Boolean	Whether the setting is locked for user to overwrite it
modified	TimeStamp	automatically created timestamp of last change

8.6 Satellite Database

The satnms4 backend stores all information about satellites, antenna pointing, ephemeris data etc. In a SQL database which is accessible through the backend's API. The following paragraphs describe the table structure of the database and the meaning of each particular table column as an appendix to the API description given above.



stream_keys

8.6.1 Table Satellites (satellites)

All satellites known to this system. Number may vary from a dozen to hundreds.

Field	null	Description
satellite_id	no	unique, primary key, auto increment
name	no	free text, typically the name as given by satellite operator
operator_id	yes	1:1 relation to table *satellite-operators*
norad_number	yes	unique name (world wide standardized), 1:1 relation to table *norad_tle*
int_designator	yes	unique name (world wide standardized)
orbit_position	yes	satellite orbit position in degrees
inclination	yes	satellite inclination in degrees
alias	yes	free text, can be used by customer to add own name
modified	no	automatically created timestamp of last change

8.6.2 Table Satellite Operators (satellites_operators)

All satellites operators known to this system. Usually only a small number (2-10) but not limited to this.

Field	null	Description
operator_id	no	unique, primary key, auto generated
name	no	free text, company name of satellite operator
contact	yes	free text, multiline, hotline phone, e-mail etc.
modified	no	automatically created timestamp of last change

8.6.3 Antennas (antennas)

All antennas known to this system. Usually only a small number (2-10) but not limited to this.

Field	null	Description
antenna_id	no	unique, primary key, auto generated

Field	null	Description
devicename	no	free text, max. 11 characters (at the moment) because it is a device name from the MNC system
alias	yes	free text, can be used by customer to add own name
modified	no	automatically created timestamp of last change

8.6.4 Table Satellite Beacons (satellite_beacons)

All satellites beacons known to this system. Normally every satellite has one or more beacon signals, but it is not necessary to store these information because its only needed if you have to track the satellite. So this table could be completely empty.

Field	null	Description
beacon_id	no	unique, primary key, auto generated
satellite_id	no	ID of the satellite this beacon belongs to
frequency	no	beacon frequency, 3 digits precision (MHz)
polarization	no	integer coded receive polarization
attenuation	yes	an attenuation value to be set at the beacon receiver
default	no	boolean, true meaning this is the default beacon for this satellite
modified	no	automatically created timestamp of last change

8.6.5 Table Satellite TC (satellite_tc)

All satellite telecommand frequencies / channels known to this system. Every satellite may have one or more TC channels, but these are only required if the application deals with satellite TT&C.

Field	null	Description
tc_id	no	unique, primary key, auto generated
satellite_id	no	ID of the satellite this telecommand channel belongs to
frequency	no	TC signal frequency, 3 digits precision (MHz)
polarization	no	integer coded transmit polarization
attenuation	no	an attenuation value to be set at the TC transmitter

Field	null	Description
default	no	boolean, true meaning this is the default beacon for this satellite
modified	no	automatically created timestamp of last change

8.6.6 Table Satellite TM (satellite_tm)

All satellite telemetry frequencies / channels known to this system. Every satellite may have one or more TM channels, but these are only required if the application deals with satellite TT&C.

Field	null	Description
tm_id	no	unique, primary key, auto generated
satellite_id	no	ID of the satellite this telemetry channel belongs to
frequency_1	no	primary receive frequency, 3 digits precision (MHz)
frequency_2	no	secondary receive frequency, 3 digits precision (MHz)
polarization_1	no	integer coded primary receive polarization
polarization_2	no	integer coded secondary receive polarization
attenuation_1	no	attenuation value to be set at the primary telemetry receiver
attenuation_2	no	attenuation value to be set at the secondary telemetry receiver
default	no	boolean, true meaning this is the default beacon for this satellite
modified	no	automatically created timestamp of last change

8.6.7 Table Satellite Positions (satellite_positions)

This tables stores an antenna position (Azimuth/Elevation/Polarization) for a given Satellite and a specific Antenna.

Field	null	Description
position_id	no	unique, primary key, auto generated
satellite_id	no	ID of the satellite this position belongs to
azimuth	yes	antenna azimuth position in degrees
elevation	yes	antenna elevation position in degrees

Field	null	Description
polarization	yes	antenna polarization position in degrees
satellite-colocation	yes	TODO we need to recap how this field will be used, for now its just free text
target_number	yes	a target number for this satellite to command at the antenna controller (device specific)
antenna_id	no	id of antenna, 1:1 relation to *antenna* table
default	no	boolean, true meaning this is the default satellite position
modified	no	automatically created timestamp of last change

Should later provide a dropdown list with the valid antenna (device) names.

8.6.8 Table Table Tracking (table_tracking)

This tables stores "table tracking" files names for satellites. It could have none or one filename per satellite.

Field	null	Description
tabletracking_id	no	unique, primary key, auto generated
filename	no	free text
satellite_id	no	ID of the satellite this tracking table belongs to
default	no	boolean, true meaning this is the default table track
comment	yes	free text
modified	no	automatically created timestamp of last change

8.6.9 Table Intelsat 11 Parameters (intelsat_11parameters)

This tables stores "Intelsat 11 Parameter Sets" for satellites. It could have none or one entry per satellite.

Field	null	Description
i11_id	no	unique, primary key, auto generated
satellite_id	no	ID of the satellite these I11 parameters belong to
i11_name	no	free text, name of I11

Field	null	Description
i11_data	no	free text, (raw) data of I11 (not split into 11 single parameters)
default	no	boolean, true meaning this is the default table track
comment	yes	free text
modified	no	timestamp, generated by database at creation time

8.6.10 Table Norad TLE (norad_tle)

This tables stores "Norad Two Line Elements (TLE) " for satellites. It could have none or one entry per satellite.

Field	null	Description
norad_number	no	unique Norad Number, primary key, defined by the satellite
tle_name	no	free text, name of TLE
tle_line1	no	free text, first line of TLE
tle_line2	no	free text, second line of TLE
default	no	boolean, true meaning this is the default table track
comment	yes	free text
modified	no	timestamp, generated by database at creation time

8.6.11 Table Channels (channels)

This tables stores satellite channel records as described below.

Field	null	Description
channel_id	no	A unique ID of this ChannelData record (auto generated).
satellite_id	no	The ID of the satellite this ChannelData record refers to.
name	no	The user defined channel name.

Field	null	Description
full_name	no	The full name of this channel as it appears as a selection in the user interface. The full name is built from the satellite's name, a '-' character and the *name* field in this record. The full name must be unique because the operator selects satellite channels by this name. With POST or PATCH calls to the channel database the backend ignores this field, it automatically generates the *fullName* from the satellite name and *name* .
user	yes	The name of the user who lastly edited the channel
program_title	yes	Name of the program transmitted or received with this channel
comment	yes	A one line comment describing this satellite channel
rx_frequency	yes	The receive frequency in MHz (3 digits precision)
rx_polarization	yes	The receive polarization, one of 'X', 'Y', 'L' or 'R'
tx_frequency	yes	The transmit frequency in MHz (3 digits precision)
tx_polarization	yes	The transmit polarization, one of 'X', 'Y', 'L' or 'R'
dvb_mode	yes	The DVB mode, one of 'DVBS', 'DVBS2', 'NS3' or 'NS4'
nlc_mode	yes	The NLC mode, one of 'OFF' or 'ON'
symbol_rate	yes	The symbol rate in Msym/sec (4 digits precision)
fec	yes	The FEC rate, one of 'AUTO', '1/2', '1/3', '1/4', '2/3', '3/4', '2/5', '3/5', '4/5', '5/6', '6/7', '7/8', '8/9' or '9/10'
modulation	yes	The modulation type, one of 'BPSK', 'QPSK', 'OQPSK', '8PSK', '16PSK', '16QAM', '64QAM', '256QAM', '16APSK' or '32APSK'
rolloff	yes	The roll off factor, one of '0.02', '0.05', '0.10', '0.15', '0.20', '0.25' or '0.35'
pilots	yes	The pilots on/off switch, one of 'OFF' or 'ON'
bit_rate	yes	The data rate in Mbit/sec (4 digits precision)
use_rate	yes	Selects the way the data rate is specified, one of 'SYMBOLRATE' or 'BITRATE'
packet_size	yes	The packet size, one of '188' or '204'

Field	null	Description
frame_size	yes	The frame size, one of 'SHORT' or 'NORMAL'
video_rate	yes	The video data rate in Mbit/sec (4 digits precision)
vr_auto	yes	The video rate auto switch, one of 'FIXED' or 'AUTO'
profile	yes	The video encoding profile, one of 'MPEG2-MP@ML-420', 'MPEG2-MP@LL-420', 'MPEG2-HP@ML-422', 'MPEG2-HP@LL-422', 'MPEG2-SP@LL-420', 'MPEG2-SP@ML-420', 'MPEG2-MP@H14-420', 'MPEG2-MP@HL-420', 'MPEG2-HP@H14-422', 'MPEG2-HP@HL-422', 'MPEG2-HP@HL-420', 'MPEG2-HP@H14-420', 'MPEG2-HP@ML-420', 'MPEG4-BP@L2-420', 'MPEG4-BP@L3-420', 'MPEG4-BP@L4-420', 'MPEG4-MP@L3-420', 'MPEG4-MP@L4-420', 'MPEG4-MP@L4.2-420', 'MPEG4-HP@L3-420', 'MPEG4-HP@L4-420', 'MPEG4-HP@L4.2-420', 'MPEG4-HP@L3-422', 'MPEG4-HP@L4-422' or 'MPEG4-HP@L4.2-422'
eirp	yes	The transmit EIRP in dBW (2 digits precision)
red_eirp	yes	The reduced EIRP for line up in dBW (2 digits precision)
auto_lineup	yes	Configures automatic line up, one of 'OFF' or 'ON'
audio_rate_1	yes	Audio channel 1 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audio_rate_2	yes	Audio channel 2 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audio_rate_3	yes	Audio channel 3 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audio_rate_4	yes	Audio channel 4 data rate, one of 'DISABLED', '64k', '96k', '128k', '160k', '192k', '224k', '256k', '320k' or '384k"
audio_channels	yes	Number of audio channels, (integer, 1-4)
decoder_input	yes	Decoder input, one of 'SAT', 'IP' or 'ASI'
ip_type	yes	IP addressing type, one of 'UNICAST' or 'MULTICAST'
ip_protocol	yes	IP protocol, one of 'UDP', 'RTP', 'TCP' or 'ZIXI'

Field	null	Description
ip_source_address	yes	Source IP address in dotted quad notation
ip_source_port	yes	Source port number (integer, 0-65535)
ip_destination_address	yes	Destination IP address in dotted quad notation
ip_destination_port	yes	Destination port number (integer, 0-65535)
ip_fec	yes	IP FEC selection, one of 'OFF' or 'ON'
ip_buffer_size	yes	Buffer size (integer)
encoder_phys_interface	yes	Encoder physical output number (integer, 1-4)
decoder_phys_interface	yes	Decoder physical input number (integer, 1-4)
modified	no	automatically created timestamp of last change

8.6.12 Table StreamKeys (stream_keys)

This table stores stream keys (BISS keys, SRT passwords) as described below.

Field	null	Description
key_id	no	A unique ID of this StreamKeyData record (auto generated).
name	no	The user defined name of this stream key. This name also must be unique because the operator selects the key by this name.
type	no	The key type, one of 'BISS-1', 'BISS-E' or 'PASSPHRASE'.
key	no	The key value associated with the id and name in this record. For biss keys this is a string entirely consisting of the hexadeximal characters 0123456789ABCDEF, it is either 12 or 16 characters long. For other key types the key is free text.
modified	no	automatically created timestamp of last change

8.6.13 Table BeaconAttenuations (beacon_attenuations)

This table stores the attenuation values for a particular beacon / antenna combination

Field	null	Description
beacon_attn_id	no	A unique ID of this record (auto generated).
beacon_id	no	The ID of the beacon this attenuation belongs to.

Field	null	Description
antenna_id	no	The ID of the antenna this attenuation belongs to,
attenuation	no	The attenuation value (dB)
modified	no	automatically created timestamp of last change

8.6.14 Table TcAttenuations (tc_attenuations)

This table stores the attenuation values for a particular TC channel / antenna combination

Field	null	Description
tc_attn_id	no	A unique ID of this record (auto generated).
beacon_id	no	The ID of the beacon this attenuation belongs to.
antenna_id	no	The ID of the antenna this attenuation belongs to,
attenuation_1	no	The upconverter attenuation value (dB)
attenuation_2	no	The HPA attenuation value (dB)
modified	no	automatically created timestamp of last change

8.6.15 Table TmAttenuations (tm_attenuations)

This table stores the attenuation values for a particular TM channel / antenna combination

Field	null	Description
tm_attn_id	no	A unique ID of this record (auto generated).
beacon_id	no	The ID of the beacon this attenuation belongs to.
antenna_id	no	The ID of the antenna this attenuation belongs to,
attenuation_1	no	The primary TM signal attenuation value (dB)
attenuation_2	no	The secondary TM signal value (dB)
modified	no	automatically created timestamp of last change

8.6.16 Table InventoryItems (inventory_items)

The table inventory_items stores the properties of all items known to the inventory database.

Field	null	Description
item_id	no	A unique ID of this record (auto generated).
serial_no	yes	The serial number of the item / device
vendor	yes	The vendor name (for search filters)
model	yes	The model name (for search filters)
state	no	The administrative state of the device
comment	yes	free text
modified	no	automatically created timestamp of last change

8.6.17 Table InventoryDevices (inventory_devices)

The table inventory_devices stores the device mappings of all items known to the inventory database.

Field	null	Description
device_id	no	A unique ID of this record (auto generated).
item_no	yes	The ID of the item this device is mapped to
mnc_name	yes	The M&C name
device_name	yes	The device name
state	no	The administrative state of the device
online	yes	Boolean flag indicating if the device is online
modified	no	automatically created timestamp of last change

8.6.18 Table InventoryLog (inventory_log)

The table inventory_log stores the live cycle logs of all items which are registered in the inventory_items table.

Field	null	Description
entry_id	no	A unique ID of this record (auto generated).
item_id	no	Links to the inventory_items entry this log entry refers to.

Field	null	Description
mnc_name	yes	The M&C which issued this message or null if the message was entered at the UI
dev_name	yes	The satnms device name which issued this message
message	no	the message text
created	no	timestamp, generated by database at creation time

8.6.19 Table Documents (documents)

The table documents stores information about the documents (pdf, png, jpg) stored in the backend.

Field	null	Description
document_id	no	A unique ID of this record (auto generated).
file_name	no	Name of the file.
content_type	no	Content type of the file. must be one of application/pdf, image/png or image/jpg.
driver	yes	The satnms driver name this document refers to or null if it does not refer to a driver / device type.
mnc_name	yes	The M&C name this document refers to or null if it does not refer to a M&C.
comment	yes	free text
modified	no	automatically created timestamp of last change

The backend handles three types of documents:

- 'M&C related' documents refer to a particular M&C. They have the 'mnc_name' field set.
- 'Driver related' documents refer to a particular device type / driver. They have the 'driver' field set.
- 'global' documents do not refer to anything

Documents are stored on the backend machine in a common directory tree. Global documents are stored at the root of this tree. For each M&C and for each device driver the backend creates a subdirectory. M&C or driver related documents are stored in one of these subdirectories. File names must be unique within the subdirectory where they are are stored.

8.6.20 Table GlobalSettings (globalSettings)

The global_settings stores the properties of changed settings from default by admins.

Field	null	Description
settings_id	Integer	A Unique Id of an setting
key	no	Setting name as key
value	no	Value of the setting
username	yes	Username to which the setting belongs
isLocked	no	Whether the setting is locked for user to overwrite it
modified	no	timestamp, generated by database at creation time

8.6.21 Table User Settings (userSettings)

The user_settings stores the properties of changed settings from default by user.

Field	null	Description
settings_id	Integer	A Unique Id of an setting
key	no	Setting name as key
value	no	Value of the setting
username	yes	Username to which the setting belongs
isLocked	no	Whether the setting is locked for user to overwrite it
modified	no	timestamp, generated by database at creation time

8.7 Fonts

The satnms software uses a number of predefined fonts to be used in the user interface. The table below shows which font types / sizes match the pixel by pixel position and size values of existing screen definitions.

Name	Font	Size	Style
small	Arial	10px	PLAIN
plain	Arial	12px	PLAIN
bold	Arial	12px	BOLD

Name	Font	Size	Style
title	Arial	16px	BOLD
huge	Arial	28px	PLAIN
typewriter	Courier New	10px	PLAIN

9 Device Driver Descriptions

The following pages describe all device drivers coming with the sat-nms software. Each device driver description contains a short paragraph about what type of equipment this driver is for and how should be configured that it works seamlessly with the device.

This manual contains three tables which give you fast access to the device driver documentation:

- Device Drivers By Name --- contains a table which lists all device drivers sorted by their driver name.
- Device Drivers By Vendor --- contains a table which lists all device drivers sorted by the name of the vendor of the device to control
- Device Drivers By Tag --- contains a table which lists all device drivers sorted by tags assigned to the device drivers. These tags classify devices to groups like HPAs, antenna controllers, IRDs and more.

9.1 Device Drivers By Name

Driver	***Version***	***Vendor***	***Tags***
Acorde-ACRS-IDU	1.00 250916	Acorde Technologies	Redundancy-Controller LNA/LNB-Controller
Acorde-BUC-ACCVT	1.06 240807	Acorde Technologies	Block-Upconverter
ACTi-ACM1231-Webcam	1.03 171212	ACTi	Camera
Actia-Sodielec-DNT-HPA	1.08 240314	Actia-Sodielec	HPA TWTA
Actia-Sodielec-DSS1300	1.02 171212	Actia-Sodielec	I/O-Controller
Adtec-Afiniti-Decoder	1.01 220423	Adtec	IRD
Adtec-Afinity-Encoder	1.03 230202	Adtec	Encoder
Adtec-EN81	1.11 210916	Adtec	Encoder Modulator
Adtec-RD60	1.08 171212	Adtec	IRD

Driver	Version	Vendor	Tags

9.4 Logical Devices Overview

The sat-nms software contains a set so called logical devices, which in fact are software solution to solve different task in an M&C system.

The following list provides an overview about all these devices and the link to a detailed description.

- Antenna-Pointing --- A 'high level' driver for motor driven antennas. It is used together with a driver for the type of antenna controller used.
- Antenna-TrackingA 'high level' driver for motor driven antennas combined with step track software.
- Band-Pol-4-To-1 --- Controls a 4-to-1 switch which typically selects a receiver input signal from two polarization panes and two frequency bands.
- Channel-Select --- Channel Database
- Choice-Translator --- Provides a 2-way translation table for choice parameters.
- Device-CopyLets the operator copy the settings from one device to another with a single mouse click.
- Device-Mirror --- Ties two 1:1 redundant devices together. Any time a setting is changed at the primary device, the Device-Mirror copies this setting to the spare device.
- Dual-Translator --- Translates a set of user definable choices into the position settings of two switches (or equivalent). It may be used to combine two switches to a single function in the user interface.
- Fault-Array --- Combines fault messages or other state parameters of arbitrary devices in a flexible way to one common fault state.
- File-Recorder --- Provides a simple facility to write measurement or state values in regular intervals to a file.
- Frequency-Split --- Splits up a frequency value in a coarse part (1 MHz resolution) and a

fine part.

- Gate-Array --- Provides 8 logical gates with 8 inputs each. May be used to generate changing colors of user user interface elements due to state changes.
- IRD-Chain --- Controls the basic parameters of an IRD and an input switch for the IRD which selects frequency band and polarization
- Level-Control --- Provides a gain setting linearizer for TWT amplifiers as well as a level control loop mode.
- Level-Set --- Provides a simple mechanism to set (and monitor) transmit power values in EIRP
- Link --- Connects the equipment used in a VLC for one end point of a satellite link to the link management of the NMS software. It controls the timing when links are going up or down and does all equipment settings necessary for the satellite link.
- Logger --- Watches an arbitrary parameter and, writes a message to the event log every time the parameter value changes.
- Logical-Gate-3 --- Provides a 3-input logical gate which can be used to merge status variables in a user programmed way.
- Logical-Gate --- Provides a simple 2-input logical gate which can be used to merge status variables in a user programmed way.
- Macro-Player --- Plays a macro if the value of a watched parameter changes in a certain way.
- Modcod-Splitter --- Makes a combined MODCOD parameter controllable through individual DVB-mode, modulation-type and FEC parameters.
- Parameter-Mirror --- Ties a single parameter of two 1:1 redundant devices together. Any time the parameter is changed at the primary device, the Parameter-Mirror copies this setting to the spare device.
- Pointing-Lock --- Checks the lock state of up to twenty IRD-Chain devices and controls the enable state of one Antenna-Pointing device.
- Protection-Switch-1-To-1 --- Provides a completely software based solution for a 1:1 redundancy switch. The logical device monitors the fault states of a couple of devices, deriving from this the information whether to switch the (usually transmit-) chain.
- Protection-Switch-2-To-1 --- Provides a completely software based solution for a 1:1 redundancy switch. The logical device monitors the fault states of a couple of devices, deriving from this the information whether to switch the (usually transmit-) chain. This device is contained for compatibility to existing sat-nms installations. For new installations the N:1 redundancy switch described below should be used.
- Protection-Switch-N-To-1 --- Provides a completely software based solution for a N:1 redundancy switch for transmit chains. Supersedes the Protection-Switch-2-To-1 device.
- Proxy-Device --- Maps a device from a remote sat-nms M&C onto the local system.
- Remote-Alarm --- The Remote-Alarm logical device is part of the remote alarm client feature of the software which reports failures of a M&C system to a remote site through a ('on demand') dial up connection.
- Replicator --- Replicates a parameter setting from one device to another.
- RX-ChannelSelect --- Applies tuning parameters and input signal selection from a common channel database to an IRD, including LO frequency calculations for multiple antennas.
- RX-ChannelSelect-CDB --- Similar to RX-ChannelSelect, but for usage in an NMS environment, using a central database (CDB) located in the NMS server for the channel lists.

- SNG-Pointing --- Adds some useful functions to the basic control of car mounted antennas.
- Site-Switch --- Implements a site diversity switch control and is mostly used to backup up-link facilities at different sites.
- Switch-Cross-Link --- Translates a ON/OFF command into a set of arbitrary messages / commands.
- Sync-Switch --- Couples two switches located at two different site to one single switch.
- Transmit-Chain-Preset --- Manages to store / retrieve the settings of a complete transmit chain in one preset. The device collects the setting of a polarization switch, the frequency and the EIRP of the transmission and the device presets of two arbitrary devices (e.g. modulator and encoder) into one DevicePreset.
- TX-ChannelSelect --- Applies tuning parameters from a common channel database to an encoder / modulator.
- TX-ChannelSelect-CDB --- Similar to TX-ChannelSelect, but for usage in an NMS environment, using a central database (CDB) located in the NMS server for the channel lists.

9.6 APC-ATS

This page describes the device driver and the device window for APC Automatic Transfer Switches via SNMP.

The driver was tested with the following models:

- AP4421 SW: 4.34
- AP7723 SW: 3.05

NOTE: Please enable SNMP access (v1) and set read/write community via WebUI

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The device control parameters
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
    - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
    - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.

  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- frontPanel --- Defines number of available channels
- voltageSensitivity --- Defines units voltage sensitivity HIGH/LOW
- voltageRange --- Defines units voltage range WIDE/MEDIUM/NARROW
- currentLimit --- Defines units current limit (0..20A)
- lineVrms --- Defines line VRMS in V
- wideVrms --- Defines wide VRMS in V
- mediumVrms --- Defines medium VRMS in V
- narrowVrms --- Defines narrow VRMS in V
- freqDeviation --- Defines frequency deviation in Hz
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

9.7 APC-RPDU

This page describes the device driver and the device window for APC rPDU series PowerModules via SNMP.

The driver was tested with the following models:

- AP7920

NOTE: Please set SNMP write community access rights to "write+" within WebUI of APC to allow on/off/reboot

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The device control parameters
- --- The faults page.

- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- pulseTime.01 --- Defines the pulse time in sec for outlet 1
- pulseTime.02 --- Defines the pulse time in sec for outlet 2
- pulseTime.03 --- Defines the pulse time in sec for outlet 3
- pulseTime.04 --- Defines the pulse time in sec for outlet 4
- pulseTime.05 --- Defines the pulse time in sec for outlet 5
- pulseTime.06 --- Defines the pulse time in sec for outlet 6
- pulseTime.07 --- Defines the pulse time in sec for outlet 7
- pulseTime.08 --- Defines the pulse time in sec for outlet 8

9.8 APS-Backup-Antenna-Control

The APS-Backup-Antenna-Control logical device is a project specific extension to the sat-nms software. The device controls the switch over procedure between a backup antenna and a number of operative antennas.

Switching the uplink from an operative antenna to the backup antenna is a 2-step procedure. The first step (preparation) positions the backup antenna to the same satellite as the operative antenna and prepares the waveguide switches at the backup antenna for taking over the signal(s) from the operative antenna.

After the preparation has been completed successfully the final switchover is executed as an independent command. The actual switchover is performed by a APS-Backup-Antenna-Switch logical device located at the operative antenna. This sets the waveguide switches there to route the uplink to the backup antenna instead to the local one. Immediately after the switchover this device also increases the transmit power to compensate for the increased waveguide loss to the backup antenna. At the backup antenna M&C, Proxy devices act in place of the remote APS-Backup-Antenna-Switch devices.

Antenna command and verification

As of version 2.00 the APS-Backup-Antenna-Control device expects the backup antenna to be controlled by a SatService ACU/ODM (SatService-ACU-ODM device driver). During the switchover preparation phase, the APS-Backup-Antenna-Control device commands a target memory number to the ACU/ODM. The target memory in the ACU contains the center of box coordinates of the satellite and the beacon/tracking parameters stored for the satellite normally tracked by the antenna which is going to be backed up.

The center of box coordinates are stored in the APS-Backup-Antenna-Control device's configuration file as well. After the the antenna has been commanded to move to the target in question, the APS-Backup-Antenna-Control device polls the actual antenna pointing and compared it to the pointing stored in the configuration file. Once the pointing matches within a

configurable threshold, the APS-Backup-Antenna-Control device states "position reached" and proceeds to the next step.

With this next step the beacon level threshold fault is monitored. The device waits until there is no beacon level stated by the ACU, then the device assumes the antenna points to the satellite.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands the signal destination setting.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters from this page are described below.

Configuration parameters

Most of the configuration parameters of the APS-Backup-Antenna-Control device are defined in a configuration file (see below). At the maintenance page of the device window there are a couple of configuration parameter which concern the local (backup) antenna device.

parameter	***description***
antennaName	The device name of the backup antenna controller. This device must be a NDSatCom-Step-Track device.
antennaTimeout	The maximum time, the APS-Backup-Antenna-Control device waits after an antenna movement, that the antenna tracks the new satellite.
azThreshold	The difference between measured and commanded antenna pointing accepted by the APS-Backup-Antenna-Control device to state 'position reached'.
elThreshold	The difference between measured and commanded antenna pointing accepted by the APS-Backup-Antenna-Control device to state 'position reached'.

Fault flags

The device provides three fault flags:

- The 'Configuration file FAULT' is set if the device could not parse it's configuration file on startup.
- The 'Switch combination FAULT' is set if the combination of waveguide switch settings does not match any of the configured combinations. Command a 'prepare', optionally followed by a 'release' to reset this fault.

- The 'Switchover procedure FAULT' is set if a fault occurs during a prepare or switchover procedure. The 'reset' command clears this fault.

Configuration file

The APS-Backup-Antenna-Control device requires to be setup by a configuration file. The file has the name of the device (case sensitive!) extended by the suffix '.txt'. The file must reside in the M&C server's home directory. It defines the number of stations this antenna shall backup, the antenna pointings and all switch setting to be performed during the preparation / switchover.

The file format text based, straight forward and almost self-explaining. This is a short example, taken from the real installation in Munich. Everything right of a '#' character is treated as a comment, in the example below those are used used to describe the file format.

```
#
#  Example for an APS-Backup-Antenna-Control configuration file
#
#
   S1-2X = A    # WG switch setting for the local operation
   S1-2Y = A    # of the backup antenna. The 'forceLocal' command
   S1-3X = A    # tells the APS-Backup-Antenna-Control to perform
   S1-3Y = A    # these settings
   S2-1X = A
   S2-1Y = A
   S1-AX = B
   S1-AY = B
   S2-AX = B
   S2-AY = B

#  The 'station' statement opens the definition of a antenna / M&C to backup.
#  '1A' is the name of the antenna which appears in the selection box a the
#  APS-Backup-Antenna-Control's user interface.
#
station 1A

   S1-2X = B    # The WG switch settings following the 'station' statement
   S1-2Y = B    # are performed when the operator commands to prepare the
   S1-3X = B    # take over for this antenna. They are performed immediately,
   S1-3Y = B    # before the antenna gets moved.

   # The 'antenna' statement tells the device where to point the antenna. It
   # must be followed by the target memory number to be invoked at the
   # antenna controller and the azimuth / elevation reference angles on
   # the same line.
   #
   antenna  2  169.958  34.115
```

```
    SU-4X = B    # After the antenna has been pointed to the new satellite and
    SU-4Y = B    # tracking has found the satellite, the WG switch settings
    SU-3X = B    # following the 'antenna' statement are performed. After
    SU-3Y = B    # these settings have been verified successfully, the
    S1-AX = A    # backup antenna is prepared for the switchover.
    S1-AY = A

    # The 'final' statement closes the definition opened by 'station'. It
    # tells the APS-Backup-Antenna-Control device which proxy device
    # has to be controlled in order to execute the actual switchover at the
    # remote antenna. The proxy device must be configured to act for the
    # APS-Backup-Antenna-Switch device at the M&C of interrest.
    #
    final ASTRA-1A

#  Here starts the definition of the second station (omitted here). The
#  APS-Backup-Antenna-Control device is capable to manage an arbitrary number
#  of stations.
#
station 1B
```

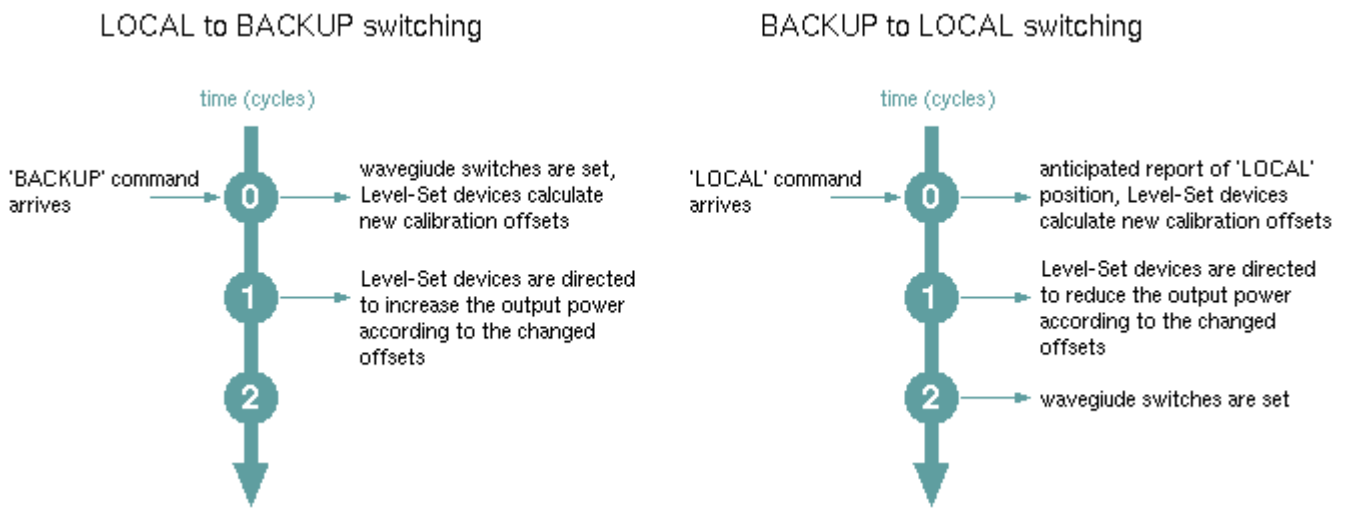
9.9 APS-Backup-Antenna-Switch

The APS-Backup-Antenna-Switch logical device is a project specific extension to the sat-nms software. The device controls the signal path to from the HPAs / power combiners to the antenna. For this the device commands a number of wave guide switches. The device names of the switches are configurable as the individual switch positions are as well. The APS-Backup-Antenna-Switch device is used in conjunction with the APS-Backup-Antenna-Control device which manages the sequence of operations required to switch an antenna's transmit signal to the backup antenna.

The APS-Backup-Antenna-Switch provides three signal destination choices:

- **LOCAL** --- The transmit signal gets routed to the local antenna.
- **BACKUP** --- The transmit signal gets routed to the backup antenna. The wave guide switches at the backup antenna *must* have been set to the proper positions before.
- **DUMMY** --- The transmit signal gets routed to a dummy load. It depends on the configuration of the APS-Backup-Antenna-Switch if this destination selection is available for a particular antenna.

One task of the APS-Backup-Antenna-Switch device is to manage the individual waveguide switch settings necessary for the procedure to switch to the backup antenna and back up the local one. The other task of the device is to let the Level-Set devices attached to each HPA know about the actual signal path and to command them to adjust the power at the right time. The sequence of operations is as shown in the diagram below:



When switching to BACKUP (requires a higher power at the HPAs due to the longer waveguide path), the device first sets the waveguide switches and reports the signal destination to be BACKUP. The Level-Set devices monitoring this value calculate new calibration offsets due to the change, but do not change the ouptu power. One cycle (usually 1000 msesc) later, when the switches are in the BACKUP position, the APS-Backup-Antenna-Switch commands the Level-Set devices to increase the output power according to the changes calibration values.

When switching to LOCAL (this requires to reduce the output power), the device first reports the LOCAL setting although the waveguide switches have not yet been set. This causes the Level-Set device calculate the calibration offsets for the LOCAL signal path. One cycle later the output power reduction is commanded. In a third cycle the APS-Backup-Antenna-Switch device sets the waveguide switches to the LOCAL.

Switching the signal destination to DUMMY (dummy load) does not cause a change of the amplifiers' output power remains.

Destination monitoring

At power on, the APS-Backup-Antenna-Switch detects the actual destination selection from the waveguide switch positions (they are the 'permanent' memory for this parameter). If the combination of the switch positions is not valid (does not match any of the switch combinations defined with the configuration parameters), a fault flag is set.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands the signal destination setting.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters from this page are described below.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameter which must be set to interconnect the device with the switches that will perform the signal routing.

parameter	***description***
lsetNames	A comma separated list of devices names. Each device must be a Level-Set device which shall receive an 'adjustDrive' command during the switchover sequence as described above. This list may be empty if there are no Level-Set devices to control.
Example: **EIRP-1,EIRP-2,EIRP-3,EIRP-R**	
swNames	A comma separated list of devices names. Each device must be a 'switch' type in that way, that is provides a variable called 'position' which selects the signal path.
Example: **S01,S02,S03,S04**	
swLocal	A comma separated list defining the switch commands (positions) which get applied when the device switches to the LOCAL position. The number of items in the list must match the number of switches defined above. Switches and position commands are linked by their position in the list.
Example: **A,A,B,B**	
When switching to LOCAL, S01 and S02 are set to position 'A', S03 and S04 are set to 'B' following this example.	
swBackup	A comma separated list defining the switch commands (positions) which get applied when the device switches to the BACKUP position. The number of items in the list must match the number of switches defined above. Switches and position commands are linked by their position in the list.
Example: **B,B,A,A**	
When switching to BACKUP, S01 and S02 are set to position 'B', S03 and S04 are set to 'A' following this example.	

parameter	***description***
swDummy	A comma separated list defining the switch commands (positions) which get applied when the device switches to the DUMMY position. The number of items in the list must match the number of switches defined above or the field must be left empty. Switches and position commands are linked by their position in the list.
Example: **A,B,A,B**	
When switching to DUMMY, S01 and S03 are set to position 'A', S02 and S04 are set to 'B' following this example. If the field is left empty, the devices suppresses the DUMMY destination.	

Changes of the configuration parameter are recognized immediately. If this temporarily leads to invalid switch combinations, the 'Switch position match FAULT' is set. It may be necessary to switch the 'position' parameter once in order to clear this fault.

Fault flags

The device provides two fault flags:

- The 'Switch position match FAULT' is set if the actual positions of the waveguide switches do not match any of the combinations configured for this device. This may happen with a defective switch or if a switch is controlled manually. The fault disappears when the switch position gets fixed.
- The 'Switch hardware FAULT' is set if at least one of the switch devices has it's summary fault set.

Configuration hints

To make the APS-Backup-Antenna-Switch device interact properly with a Level-Set device, both devices mut be configured as follows:

- The Level-Set device must have the 'position' variable of the APS-Backup-Antenna-Switch set at either the 'txSwitch1Id' or 'txSwitch2Id' configuration setting in order to monitor the selected signal path. The Level-Set device must not monitor the waveguide switch positions directly!
- At the APS-Backup-Antenna-Switch, the name of the Level-Set device must appear in the 'lsetNames' configuration setting. This makes the APS-Backup-Antenna-Switch sending 'adjustDrive' commands to the Level-Set device during the switchover sequence.
- At the Level-Set device, the 'EIRP low/high threshold' faults should be configured with a 5 seconds delay to avoid unwanted fault messages during the switchover.

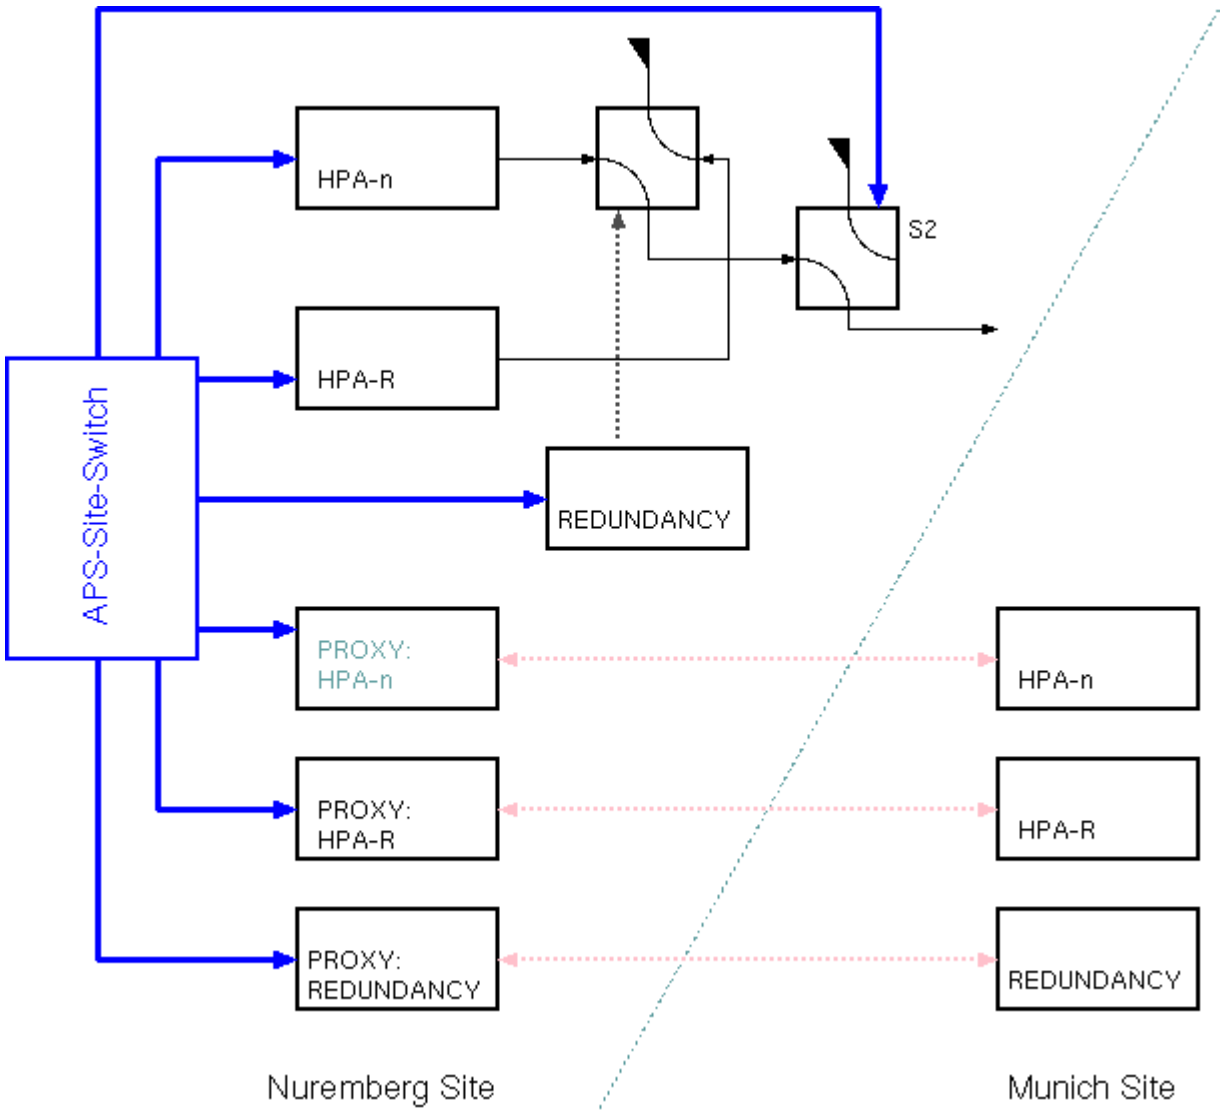
9.10 APS-Site-Switch

The APS-Site-Switch logical device is a project specific extension to the sat-nms software. The device controls the equipment of one transmit chain for the site diversity application between Nuremberg and Munich.



As shown in the figure above, the APS-Site-Switch logical device is operated at the Nuremberg site. There it controls the HPA which shall take over the Munich uplink, the redundant HPA, the protection switch logical device and the waveguide switch S2 which routes the HPA output either to dummy load or to the antenna. Beside this, the APS-Site-Switch controls three Proxy devices which must be configured to resemble the corresponding HPAs and the protection switch at the Munich site.

Site switch procedure

Switching the uplink from Munich to Nuremberg is a 2-step procedure. With the first step, Nuremberg gets prepared to take over the uplink, the real site switch then is performed as the second step.

To prepare Nuremberg to take over the uplink, the function 'prepare' performs the following operations:

1. Switch off the HPA protection / redundancy switch.
2. Detect if HPA-? or the redundant one must be used.

3. Switch the HPA of interest to RF-OFF.
4. Poll the HPA up to 10 seconds until it states RF-OFF. Abort on failure.
5. Switch the HPA BEAM-ON
6. Switch S2 to antenna.

The Nuremberg transmit facility is signalled to be prepared, when the APS-Site-Switch detects the protection switch to be OFF, the HPA to be RF-OFF / BEAM-ON and S2 set to antenna.

The actual switch over can only be performed, if the 'prepared' condition is detected by the APS-Site-Switch. This enables the 'NBG' button at the user interface. The steps of the switch over are:

1. Switch OFF protection for the Munich HPA, remember the value to restore it when switching back.
2. Detect if HPA-? or the redundant one must be used at Munich.
3. Switch the Munich HPA to RF-OFF.
4. Poll the HPA up to 10 seconds until it states RF-OFF.
5. Switch the Nuremberg HPA to RF-ON.

Switching back to Munich works the same way the other way round.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands actual uplink location.
- --- The device info page.
- --- The maintenance page. The configuration parameters from this page are described below.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameter which must be set to interconnect the device with the devices that will perform the carrier on/off settings.

parameter	***description***
s2Device	The device name of the waveguide switch which routes the local uplink either to the antenna or to a dummy load.
s2Positions	Two switch positions for the S2 switch, separated by a comma. The first value is used to switch S2 to dummy load, the second one to switch it to antenna.
lclHpaDevice	The device name of the local HPA.
lclProtectDevice	The device name of the local protection switch device.

parameter	*description*
rmtHpaDevice	The device name of the Proxy device which resembles the corresponding HPA at the Munich site.
rmtProtectDevice	The device name of the proxy device which resembles redundancy switch at the Munich site.
comment	A short text which is displayed on the main page of the device window to ease the identification of the transmit chain.

9.11 ARD-Backup-Client

The *ARD-Backup-Client* is a customer specific logical device which controls a backup transmit chain located an another M&C system using a proprietary UDP based remote control protocol. The remote backup transmit chain may be controlled by a third party M&C system implementing this protocol or by a sat-nms M&C using the ARD-Backup-Server logical device.

The *ARD-Backup-Client* shows some state information about the remote transmit chain in it's device window and provides buttons to switch this chain to antenna or to load. Beside this, buttons are provided to increment or decrement the chain's transmit power in steps of 1 or 0.5 dB.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Monitoring an control of the remote backup transmit chain
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to integrate the device into the VLC/M&C.

parameter	*description*
chainName	The name of the backup transmit chain at the remote M&C. This name is used in the communication protocol to address the chain to be controlled. Typical values are 'SZ1' or 'SZ2'

parameter	*description*
listenPort	The port number at which the ARD-Backup-Client listens for status messages from the remote M&C. This port number must match the 'clientPort' set at it's counterpart.
serverPort	The port number to which the ARD-Backup-Client sends any command messages. This port must match the 'listenPort' set at the server side.
serverIP	The IP address of the remote M&C.
key	The key used by the communication protocol to encrypt/decrypt messages. The key is a 256 digit hexadecimal string. Normally there is no need to change this parameter.
wgsId	The device name of the wave guide switch used to switch the signal either to antenna or to load. The ARD-Backup-Client expects this device to provide a 'position' parameter which controls the switch position.
wgsXlate	A comma separated list of two switch positions. The first position indicates 'LOAD', the second one 'ANTENNA'. If for example the switch routes the signal to antenna for position 'A', wgsXlate must be set to 'B,A'.
powerDetectId	The ID of a parameter which indicates if there is transmit power detected after the wave guide switch. The ARD-Backup-Client expect this to be a boolean type value with 'true' indicating the presence of transmit power at the antenna.

Fault flags

The device provides a 'faults.99' fault flag which indicates that the communication to the remote M&C is broken. The flag is raised if there was no valid status message received for 5 seconds.

Remarks

The device uses it's device thread to detect communication timeouts. For this reason, the device should be configured as the only device at a 'null' interface with an idle time of 1000 msecs.

9.12 ARD-Backup-Server

The *ARD-Backup-Server* is a customer specific logical device which monitors and controls some

parameters of a backup transmit chain and permits remote control of these parameters from another M&C system using a proprietary UDP based remote control protocol. The remote M&C may be a third party M&C system implementing this protocol or by a sat-nms M&C using the ARD-Backup-Client logical device.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows some status information.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to integrate the device into the VLC/M&C.

parameter	***description***
transponder	The name of the transponder this backup transmit chain is red for. The transponder name is part of the communication protocol and displayed as a header at the client GUI.
chainName	The name of the backup transmit chain. This name is used in the communication protocol to address the chain to be controlled. Typical values are 'SZ1' or 'SZ2'
dotlistenPort	The port number at which the ARD-Backup-Server listens for command messages from the remote M&C. This port number must match the 'serverPort' set at it's counterpart.
clientPort	The port number to which the ARD-Backup-Server sends it's status messages. This port must match the 'listenPort' set at the client side.
clientIP	The IP address of the remote M&C.
key	The key used by the communication protocol to encrypt/decrypt messages. The key is a 256 digit hexadecimal string. Normaly there is no need to change this parameter.
asiInputId	The parameter ID of the modulator's ASI input selection. The ARD-Backup-Server expects this parameter to one of '1'. '2'. If the referenced modulator parameter uses other values, a Choice-Translator device should be used to adapt the selections.

parameter	***description***
wgsId	The device name of the wave guide switch used to switch the signal either to antenna or to load. The ARD-Backup-Server expects this device to provide a 'position' parameter which controls the switch position.
wgsXlate	A comma separated list of two switch positions. The first position indicates 'LOAD', the second one 'ANTENNA'. If for example the switch routes the signal to antenna for position 'A', wgsXlate must be set to 'B,A'.
upconverterId	The device name of the upconverter in the chain.
modulatorId	The device name of the modulator in the chain.
hpaId	The device name of the HPA in the chain.
powerDetectId	The ID of a parameter which indicates if there is transmit power detected after the wave guide switch. The ARD-Backup-Server expect this to be a boolean type value with 'true' indicating the presence of transmit power at the antenna.
hpaPowerId	The parameter ID reporting the HPA output power. The referenced parameter should report the HPA output power in Watts.
dvbModeId	The parameter ID reporting the modulator's DVB-S / DVB-S2 setting. For devices using combined modcod settings see 'Remarks' below.
modulationId	The parameter ID reporting the modulator's modulation (QPSK, 8PSK etc.) setting. For devices using combined modcod settings see 'Remarks' below.
fecId	The parameter ID reporting the modulator's FEC setting. For devices using combined modcod settings see 'Remarks' below.
frequencyId	The parameter ID reporting the chain's transmit frequency (MHz). The parameter should report the real TX frequency at the antenna, no IF or L-Band frequency.
symbolRateId	The parameter ID reporting the modulator's symbol rate (Msym/sec)
dataRateId	The parameter ID reporting the modulator's interface data rate (MBit/s)
asiModeId	The parameter ID reporting the modulator's ASI mode setting (packet size)
eirpId	The ID of the parameter reporting the (measured) transmitted EIRP (dBW).

parameter	*description*
eirpFaultId	The parameter ID of a fault flag indicating that the measured EIRP values is outside it's configured limits.
pwrControlId	The ID of the parameter controlling the transmit power. The value should be dB-based, may refer to either a gain setting or to an attenuation.
pwrControlMode	Selects if powerControlId refers to an 'ATTEN' or to a 'GAIN' parameter, thus reverting the sense of the power increment buttons as required.

Remarks

The ARD-Backup-Server device sends status messages to the client on a regular basis. The device sends one message per driver cycle. Hence it is recommended to configure the device as the only one at a 'null' device. The IDLE time setting of this interface lets you control the frequency of the status message transmissions.

The device combines the state information received through the 'dvbModeId', 'modulationId' and 'fecId' parameters to a combined modcod string looking like 'DVBS-QPSK-3/4'. If the modulator already uses combined modcod settings, you may use such a parameter in place of the individual settings. If for instance the modulator used a combined modulation-fec setting, you may set this parameter at the 'modulationId' an leave the 'fecId' setting empty.

9.13 ASCSignal-NGC-ACU

This page describes the device driver and the device window for the ASC Signal NGC ACU.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the antenna pointing parameters.
- --- Contains the tracking parameters.
- --- Contains the monopulse tracking parameters if applicable.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the antenna controller.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- jogRate --- The speed used to jog the antenna (0-100%)

- jogRate --- The speed used to jog the antenna (0-100%)
- monopulse --- Enables/disables the monopulse tracking parameters.

9.14 ASCSignal-NGC-BDC

This page describes the device driver and the device window for Work Dual Band BDC integrated in ASC Signal NGC 4000 ACU.

The driver was tested with the following FW:

- FW Work: FCA02.06

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device

windows .

- RX --- Shows the units state and gain/attenuation setting
- --- Shows the temperature measurent and reference source.
- --- Page not applicable for this device.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the controller.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- readBackDelay --- Delays the read back of a parameter actually set for at least the given delay time. This shall ensure that the device has processed the new parameter before it is read back. You should leave this parameter at it's default setting.
- powerDisplayMode --- Defines the display of gain or attenuation in the parameter section.
- moduleIndex --- Sets the module index which applies for the BDC in the ACU system setup. Setting this parameter is indispensable for proper communication

9.16 ASCSignal-NGC-Hub-AC

This page describes the device driver and the device window for the hub air condition system integrated in ASC Signal NGC 4000 ACU.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows all measurements as well as the climate control units state
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the controller.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- readBackDelay --- Delays the read back of a parameter actually set for at least the given

delay time. This shall ensure that the device has processed the new parameter before it is read back. You should leave this parameter at it's default setting.

- highTempAlarm --- Defines the ambient temperatures high alarm limit.
- lowTempAlarm --- Defines the ambient temperatures low alarm limit.
- fan.setpoint --- Defines the temperature setpoint in '°C' for activating the fan.
- fan.diffSetpoint --- Defines the differential temperature setpoint in '°C' for how long the fan stays on.
- cool.setpoint --- Defines the temperature setpoint in '°C' for activating the a/c cooling.
- cool.diffSetpoint.1 --- Defines the differential temperature setpoint in '°C' for how long a/c cooling stays on.
- cool.diffSetpoint.2 --- Defines the differential temperature setpoint in °C for how long a/c cooling stays on
- heat.setpoint --- Defines the temperature setpoint in '°C' for activating the heating furnace
- heat.diffSetpoint.1 --- Defines the heating differential temperature setpoint in '°C' for how long heating furnace stays on.
- heat.diffSetpoint.2 --- Defines the heating differential temperature setpoint in '°C' for how long heating furnace stays on.
- loPressure.setpoint --- Defines the compressor low pressure alarm setpoint.
- hiPressure.setpoint --- Defines the compressor high pressure alarm setpoint.
- humidity.setpoint --- Defines the humidity cycle differential setpoint for how long furnace or cooling stay on.
- humidity.diffSetpoint --- Defines the humidity cycle setpoint
- unitA.voltage --- Defines the output voltage unit B.
- unitB.voltage --- Defines the output voltage unit B.
- switchoverTime --- Defines the auto switchover interval in fixed steps.
- compressorDelay --- Defines the compressor delay time in fixed steps.
- fanMode --- Defines the hub a/c fan mode.

9.17 ASCSignal-NGC-RedundancyModule

This page describes an addon device driver and the device window for the ASC Signal NGC ACU redundancy module

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the redundancy switching parameters
- --- Contains the LNA/LNB meter readings.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the antenna controller.

- *parameter* --- *description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
    - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
    - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
    - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
    - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If

both community names are missing, the driver uses 'public' as a default for read and write community.

- readBackDelay --- Delays the read back of a parameter actually set for at least the given delay time. This shall ensure that the device has processed the new parameter before it is read back. You should leave this parameter at it's default setting.

9.18 ASCSignal-NGC-Temperature

This page describes the device driver and the device window for up to 16 temperature sensors integrated in ASC SignalNGC 4000 ACU.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows all sensor measurements as well as their thresholds
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the controller.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted,

the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.

- readBackDelay --- Delays the read back of a parameter actually set for at least the given delay time. This shall ensure that the device has processed the new parameter before it is read back. You should leave this parameter at it's default setting.
- sens.xx.hiThreshold --- Defines the high temperature threshold in '°C' for the respective sensor.
- sens.xx.loThreshold --- Defines the low temperature threshold in '°C' for the respective sensor.

9.19 ASCSignal-NGC-Weather

This page describes the read only device driver and the device window for the ASC Signal NGC 4000 ACU integrated weather station.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows all measurements of the weather station

- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the controller.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- wind.hiThreshold --- Defines the high wind threshold in m/s. If the measured value exceeds the limit a high wind fault is raised.
- temp.loThreshold --- Defines the low temperature threshold in '°C'. If the measured value fall below the limit a low temperature fault is raised.
- temp.hiThreshold --- Defines the high temperature threshold in '°C'. If the measured value exceeds the limit a high temperature fault is raised.

9.20 Acorde-ACRS-IDU

This page describes the device driver and the device window for the Acorde LNA/LNB Redundancy System Controller via SNMP.

Tested with the following 2:1 redundancy model:

- ACRS-IDU-V1-MNU-04-00
- FW ACFIRM-M9-IDU-V218-COD-05-00

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The first parameter page displays the redundancy settings.
- --- The second page shows the voltage and current measurement values.
- --- The third page shows the voltage and current threshold values.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the controller.

parameter	***description***
address	The SNMP address specification for the device (details below).
readBackDelay	Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
model	Defines the model redundancy type: 1:1 or 2:1
remote	Sets the unit to remote or local access
hasTrackingLna	Defines if the unit is equipped with a separate tracking LNA. Set to NO by Default.
remote	Enable/Disable latched faults

SNMP address specification

The full address consists of the following fields:
`aaa.bbb.ccc.ddd:pppp read-community write-community`

parameter	description
aaa.bbb.ccc.ddd	The IP address of the device in 'dotted quad' notation. This field is mandatory.
pppp	The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
read-community	The SNMP read community name. This must match the read community expected by the device.
write-community	The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses `public` as a default for read and write community string.

9.21 Acorde-BUC-ACCVT

This page describes the device driver and the device window for the for the Acorde (dual-) block upconverter via SNMP.

It was developed based on `ACCVT-LKa-Ex-Vx-MIB-01-06.mib`

- Tested with model: `ACCVT-LKa-E28-V4`
- Firmware Version: `ACFIRM-M9-CONV-V282-COD-03-20`

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- TX --- The operational parameters
- --- The meter readings. Temperature/Voltage/Current.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	**description**
address	The SNMP address specification for the device (details below).
powerDisplayMode	Defines the display of gain or attenuation in the parameter section.
extRef	Allows to switch unit between internal or external reference source, automatic mode and automatic fallback mode.
gainRange	Allows to adjust the gain range of the respective unit. The default range is 30dB.

parameter	description
deviceComment	An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The `\n` character sequence is translated into a newline character, splitting the text into multiple lines.

SNMP address specification

The full address consists of the following fields:
`aaa.bbb.ccc.ddd:pppp read-community write-community`

parameter	description
aaa.bbb.ccc.ddd	The IP address of the device in 'dotted quad' notation. This field is mandatory.
pppp	The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
read-community	The SNMP read community name. This must match the read community expected by the device.
write-community	The SNMP write communit name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses `public` as a default for read and write community.

9.22 Actia-Sodielec-DNT-HPA

This page describes the device driver and the device window for the Actia Sodielec DNT TWT amplifiers. The device driver actually supports the following models:

- Actia Sodielec DNT503C

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The operational parameters (BEAM-ON/STANDBY, RF ON/OFF)
- --- Displays meter readings like output power and TWT specific measurements.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the Amplifier.

parameter	***description***
address	The device address must be specified as a decimal number in the range 32 .. 127. The device address entered here is the address (0 ..95) set at the device plus 32.
Serial	Remember to set the line parameters for the serial interface connected to the TWTA. The factory default of the HPA is *19200,E,7,1* .

9.23 Actia-Sodielec-DSS1300

This page describes the device driver and the device window for the*Actia Sodielec DSS1300* switch controller.

The *Actia-Sodielec-DSS1300* device driver is part of the sat-nms framework for M&C of plain digital I/O functions. Monitoring alarm circuits or controlling waveguide switches are indicatives for applications of this framework.

The application configuration normally does not access the*Actia-Sodielec-DSS1300* device driver directly. There are a couple of application level logical devices (e.g. Input , Output or WG-Switch) which may use the *Actia-Sodielec-DSS1300* device driver as a low level driver to access the physical I/O ports.

Input ports

The variable 'inputs' refers to the input ports 1..16 monitored by the device. The least significant bit reports the state of input 1, the 2^15 bit reports the state of input 16.

Output ports

The variable 'outputs' is used to control the outputs of the device. The least significant bit in 'outputs' corresponds to output 1, the most significant bit to output 16.

- --- **The DSS1300 switch controller does not provide any means to read back the actual state of an output. For this reason all outputs read "0" / "inactive" after the start of the software.**

Individual output variables

Beside of using the 'outputs' variable together with the sat-nms framework for M&C of plain digital I/O functions, each output may controlled directly through an individual parameter. The variables *out01* .. *out16* accept an integer value in the range 0 .. 255 and directly perform the device's output command. The value passed to the variable select the way how to actuate the output:

value	***description***
0	switches the output OFF
1..254	generates a pulse of a defined length. The output is switched ON for*value * 10msecs* , then switched OFF again.
255	switches the output permanently ON

The individual output variables may be used to resemble the device's front panel buttons.

- --- **An application must not use the 'outputs' variable and the individual outputs at the same time. Setting individual outputs will mess up the**

behaviour of the 'outputs' variable and vice versa.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands I/O port states.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the device.

parameter	***description***
address	The device address must be specified as a decimal number in the range 32 .. 127. The device address entered here is the address (0 ..95) set at the device plus 32. Factory default of the device is 126 (94 at the device).
serial ifc	The serial interface settings must match the line parameters programmed in the device. Factory default of the device is 19200,e,7,1

9.24 Adtec-Afiniti-Decoder

This page describes the device driver and the device window for the Adtec Afiniti Decoder device via SNMP. It supports one decoding instance. For the second decoder instance another device is necessary.

Additionally it is necessary to select the slot where decoding card is installed via device setup config.slot. The dedicated decoder can be selected via config.channel.

For 4k applications that use a single Video PID the Decoder must be set to Single Mode

(channel.mode = SINGLE). In single channel mode the 4 SDI outputs will be independent and not mirrored pairs.

The unit does not support BISS Decryption.

It is necessary to preconfigure the Adtec Afiniti Decoder via the webpage:

- ASI-Inputs 'TS Mux Rate' to a suitable value
- ASI-Inputs 'Share Services with All Outputs' to 'ON'

The driver was tested with the following sw releases and it is not backwards compatible to earlier releases.

- 4.4.6

Device window pages

The following table shows which device window pages are available with this individual device type.

- --- The main decoding parameters, including service selection.
- --- The video parameters
- --- The audio parameters
- --- Faults and fault mask
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the decoder.

- *parameter --- description*

- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*

    - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
    - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
    - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
    - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
    - The read/write-community strings factory defaults are 'public' for the read community, 'adtecuser' for the write community. Hence a typical address

specification for a Adtec-Afiniti may be *10.0.0.1 public adtecuser*.

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- slot --- Defines the slot where encoding card is installed 1-6.
- channel --- Defines the used encoder for this device from the 1-4.
- output --- Defines the index of the ts output which should be allocated to the chosen decoding channel.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

9.25 Adtec-Afinity-Encoder

This page describes the device driver and the device window for the Adtec Afiniti Encoder device via SNMP. It supports RTP/UDP and SRT output.

When using UHD (channel.mode = SINGLE) encoders instances 2-4 are readonly.

Driver support one HD encoding instance. For each additional instance another device is needed. Additionally it is necessary to select the slot where encoding card is installed via device setup config.slot. The dedicated Output can be selected via config.output

The driver was tested with the following sw releases:

- 4.2.0 It is not backwards compatible to earlier releases

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the MPEG output parameter settings and the operation control.
- --- Contains RTP/UDP and SRT output parameters and statistics.
- --- Contains the conditional access (BISS) parameters.
- --- Contains video in/output parameters from the MPEG stream.

- --- Contains the parameters concerning the audio channel 1 encoding.
- --- Contains the parameters concerning the audio channel 2 encoding.
- --- Contains the parameters concerning the audio channel 3 encoding.
- --- Contains the parameters concerning the audio channel 4 encoding.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the encoder.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- slot --- Defines the slot where encoding card is installed 1-6.
- channel --- Defines the used encoder for this device from the 1-4.
- output --- Defines the index of the ts output which should be allocated to the chosen encoding channel.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

9.26 Adtec-EN81

This page describes the device driver and the device window for the Adtec EN81 video encoder family.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- RF / modulator parameters (only present for devices equipped with a modulator unit)
- --- MPEG output parameters
- --- C/A encryption parameters
- --- Video parameters
- --- Audio 1 parameters
- --- Audio 2 parameters
- --- Audio 3 parameters
- --- Audio 4 parameters
- --- The faults page.
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters

which must be set to make the software talk to the encoder.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.

The read/write-community strings may be set through the Adtec-EN81 front panel or the web interface of the device. Factory defaults are 'adtec' for the read community, 'none' for the write community. Hence a typical address specification for a Adtec-EN81 may be *10.0.0.1 adtec none* .

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- withModulator --- If the driver controls a unit equipped with an L-band modulator, you have to set this to 'YES'. This enables the modulator device screen and the parameters in it. Enabling the modulator parameters for a device without modulator will cause a communication fault.
- loFreq --- Sets the upconverter LO frequency. Please note, that this only sets the LO frequency used by the sat-nms software, the value used by the device's web interface has to be set separately. Setting the LO frequency to zero lets the driver show/set the transmit frequency in terms of L-band frequency.

9.27 Adtec-RD60

This page describes the device driver and the device window for the Adtec RD60 IRD family.

Device window pages

The following table shows which device window pages are available with this individual device type.

- --- The main receive parameters, including frequency and service selection.
- --- The conditional access parameters
- --- The video parameters
- --- The audio parameters
- --- Faults and fault mask
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the encoder.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.

The read/write-community strings may be set through the Adtec-RD60 front panel or the web interface of the device. Factory defaults are 'adtec' for the read community, 'none' for the write community. Hence a typical address specification for a Adtec-EN81 may be *10.0.0.1 adtec none* .

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized to a proved preset value which should not be changed under normal circumstances.
- 22kHz --- Turns the 22 kHz signal in the LNB supply on or off. Only effective if 22kHzAuto is set OFF.
- 22kHzAuto --- Switching this on, makes the driver controlling the 22kHz signal with the receive frequency. For frequencies above the "band edge" 22kHz gets switched on.
- lnbPower --- Switches the LNB power supply ON or OFF.
- lnbVoltage --- Selects the LNB voltage (13V/18V). Only effective if the "lnbPolSwitch" parameter is set OFF.
- lnbPolSwitch --- Selects if the LNB voltage shall be permanently set to the the value selected by "lnbVoltage" (OFF) or if the voltage shall be selected from the "polarization" parameter of the driver.
- loFreqHigh --- The high band LO frequency.
- loFreqLow --- The low band LO frequency.
- bandEdge --- The band edge frequency.
- marginThreshold --- If "state.margin" drops below this value, a "Margin" fault is generated.
- serviceHunt --- Setting this ON lets the receiver use the first available service when receiving a new signal. OFF forces the receiver to get the service with the service ID set.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n"

character sequence is translated into a newline character, splitting the text into multiple lines.

9.28 Advantech-ADAM5K

This page describes the device driver and the device window for the*Advantech ADAM5000/TCP* data acquisition unit. The device driver monitors and controls the digital inputs/outputs of various modules hosted by the ADAM5000/TCP unit. Analog or temperature sensor input functions are not covered by this driver, neither are counter/timer timer function of the some modules.

The *Advantech-ADAM5K* device driver is part of the sat-nms framework for M&C of plain digital I/O functions. Monitoring alarm circuits or controlling waveguide switches are indicatives for applications of this framework.

The application configuration normally does not access the*Advantech-ADAM5K* device driver directly. There are a couple of application level logical devices (e.g. Input , Output or WG-Switch) which may use the*Advantech-ADAM5K* device driver as a low level driver to access the physical I/O ports.

Input ports

The device driver provides eight variables I00001, I00017, I00033, I00049, I00065, I00081, I00097 and I00113 which report the actual input state of digital input modules located in the slots 1..8 of the unit.

I00001 refers to the input ports of the module in the first slot (next to the ADAM5000/TCP communication module). The least significant bit of the variable denotes the state of DI0.

The variables report the physical state if the inputs. A bit is set to '1' if the input is open or externally driven to high level. The bit reads '0' if the input is connected to GND or externally driven to low level.

The device driver always reads the input state for all eight modules, regardles if there is an input module installed in a particular slot or not. This is because reading the information in this way gives the best performance. As a side effect, the driver displays some information for slots which contain other modules than digital inputs. This information should be ignored.

Output ports

The device driver provides eight variables Q00001, Q00017, Q00033, Q00049, Q00065, Q00081, Q00097 and Q00113 which report the output state of digital/realay output modules located in the slots 1..8 of the unit.

Q00001 refers to the output ports of the module in the first slot (next to the ADAM5000/TCP communication module). The least significant bit of the variable denotes the state of DO0.

The variables report the actual state of the outputs. Writing a bit to '1' closes the relay contact / opto-coupler. Reading a '1' reports a closed contact.

The device driver always reads the output state for all eight modules, regardless if there is an output module installed in a particular slot or not. This is because reading the information in this way gives the best performance. As a side effect, the driver displays some information for slots which contain other modules than digital outputs. This information should be ignored.

Output ports are read back by the driver after the sat-nms software has changed an output bit or every 10 seconds.

Configuration settings

If used with the sat-nms framework for M&C of plain digital I/O functions, the Advantech ADAM module acts like an unprogrammed PLC device. It is intended, that the device driver processes switch settings and changes of input circuits as fast as possible. The following settings are necessary to achieve this:

- When defining the ADAM5K device in the device setup window , there must not be defined any other devices beside this module for this interface.
- The Advantech ADAM5K unit is controlled through Modbus/TCP. The device's IP address must be set as an interface name like with serial devices controlled through a network terminal adapter: "aaa.bbb.ccc.ddd:502" where 502 is the standard Modbus/TCP port number.
- The IDLE time for the interface must be set to 200 msecs for a fast response of the driver.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands I/O port states.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the device.

9.29 Advantech-ADAM6K

This page describes the device driver and the device window for the*Advantech ADAM6xxx* data aquisition module family. The device driver monitors and controls the digital inputs/outputs of various ADAM6xxx modules. Analog or temperature sensor input functions are not covered by this driver, neither are counter/timer timer function of the some modules. The driver can be used together with the following modules:

- ADAM-6018 (8 open collector outputs)
- ADAM-6050 (12 inputs, 6 outputs)
- ADAM-6051 (12 inputs)
- ADAM-6052 (8 inputs, 8 outputs)
- ADAM-6060 (6 inputs, 6 relay outputs)
- ADAM-6066 (6 inputs, 6 relay outputs)

The *Advantech-ADAM6K* device driver is part of the sat-nms framework for M&C of plain digital I/O functions. Monitoring alarm circuits or controlling waveguide switches are indicatives for applications of this framework.

The application configuration normally does not access the*AdvantechADAM6K* device driver directly (except to access the temperature readings). There are a couple of application level logical devices (e.g. Input , Output or WG-Switch) which may use the *SatService-IO-FEP* device driver as a low level driver to access the physical I/O ports.

Input ports

The variable I00001 refers to the input ports provided by the device. The least significant bit denotes the state of DI0.

The variable reports the physical state if the input. A bit is set to '1' if the input is open or externally driven to high level. The bit reads '0' if the input is connected to GND or externally driven to low level.

Output ports

The variable 'Q00001' reports the actual state of the digital outputs and also sets the output states. The least significant bit in the variable corresponds to output DO0.

Configuration settings

If used with the sat-nms framework for M&C of plain digital I/O functions, the Advantech ADAM module acts like an unprogrammed PLC device. It is intended, that the device driver processes switch settings and changes of input circuits as fast as possible. The following settings are necessary to achieve this:

- When defining the device in the device setup window , there must not be defined any other devices beside this module for this interface.
- The Advantech ADAM modules are controlled through Modbus/TCP. The device's IP address must be set as an interface name like with serial devices controlled through a network terminal adapter: "aaa.bbb.ccc.ddd:502" where 502 is the standard Modbus/TCP port number.
- The IDLE time for the interface must be set to 200 msecs for a fast response of the driver.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows / commands I/O port states.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the device.

9.30 Advantech-Genesis

This page describes the device driver and the device window for the Advantech Wireless Genesis Series Amplifier. If more than one BUC is connected to the same Control panel the respective unit can be chosen from the device setup config.unit.

Note: Please be aware that in redundant setup all driver instances should communicate to the same common POC IP address. The HPA IPs are not reachable depending on switch position. The driver is designed to work for standalone units as well as in 1:1 redundancy. Other redundancy modes are not implemented and tested

It was tested with 1:1 redundant units type GenesisB1-250KuX

- SW version 1.2.02 and 1.2.04

Device window pages

The following table shows which device window pages are available with this individual device type.

- TX --- The transmit parameters
- --- The meter readings.
- --- The redundancy switching parameters.
- --- The faults page.
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	**description**

parameter	description
readBackDelay	Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
powerDisplayMode	Defines the display of gain or attenuation in the parameter section.
deviceComment	An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.
reference	Sets the reference sources of the BUC
maxAttn	Defines units max attenuation. Default setting is 30dB
lockLevel	Sets units lock level
unit	Defines the unit number (1..6) if more than one unit is controlled

SNMP address specification

The full address consists of the following fields:
`aaa.bbb.ccc.ddd:pppp read-community write-community`

parameter	description
aaa.bbb.ccc.ddd	The IP address of the device in 'dotted quad' notation. This field is mandatory.
pppp	The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
read-community	The SNMP read community name. This must match the read community expected by the device.
write-community	The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses `public` as a default for read and write community string.

9.31 Advantech-SSPB-GCP

This page describes the device driver and the device window for the Advantech Wireless BUC via GCP (General Control panel). The SSPB itself does not provide a Ethernet interface. Therefore the driver talks with the GCP via SNMP. If more than one BUC is connected to the same Control panel the respective unit can be chosen from the device setup config.unit.

It was tested with non redundant ARMA type 160W HPAs

- SW version 57

Device window pages

The following table shows which device window pages are available with this individual device type.

- --- The operational parameters
- --- The meter readings.
- --- The redundancy switching parameters.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
- unit --- Defines the unit if more than one HPA is connected towards the GCP
- redundancy --- Defines if the unit is part of a 1:1 or 2:1 redundancy managed by the GCP or used as Standalone
- powerDisplayMode --- Defines the display of gain or attenuation in the parameter section.
- accessMode --- Switch between local and remote access
- accessLock --- Lock unit
- extRef --- Switch between internal and external reference if supported
- reference --- Switch between auto and manual reference source selection
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

9.32 Advantech-SSPB-MCP

This page describes the device driver and the device window for the Advantech Wireless BUC via a Monitor and control panel M&C 100 over serial interface. It uses the Advantech MCP protocol.

- Default TCP communication port is 10001

Default serial addresses are as following for 2:1 redundancy

- SSPA-A = 18
- SSPA-B = 19
- SSPA-S = 20

It was tested with 2:1 redundant SSPAs type: SSPA-ARMA-Cx400

Device window pages

The following table shows which device window pages are available with this individual device type.

- --- The operational parameters
- --- The meter readings.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	***description***
address	Device address for serial communication
Serial	Remember to set the line parameters for the serial interface
readBackDelay	Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.

9.35 Agilent-Spectrum-Analyzer

This page describes the device driver and the device window for HP / Agilent ESA spectrum analyzers. Actually the driver supports Agilent ESA E44xx analyzers equipped with a serial (RS232) interface. It provides a remote control of the basic parameters of the device.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The spectrum view.
- --- The main parameter page displays/controls the spectrum main analyzer settings like center frequency, span, etc. You get this page in it's own window beside the spectrum view if you click to 'SET' at the upper left corner of the spectrum view window.
- --- This page gives you access to the first 16 instrument memories of the spectrum analyzer. Clicking to 'STO x' stores the actual instrument settings to this memory place in the device. Clicking to 'RCL x' recalls the selected memory.You may use the text field between the buttons to note a comment for this particular memory place. Unless the instrument settings which are stored in the device itself, the text is stored at the VLC/M&C system. Hence, if you replace the spectrum analyzer, the stored instrument settings are gone with the replaced device, the comments however are still present.Also this page is available as a separate window. click to 'PRE' at the upper left corner of the spectrum view to launch a 'preset' window without leaving the spectrum view.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

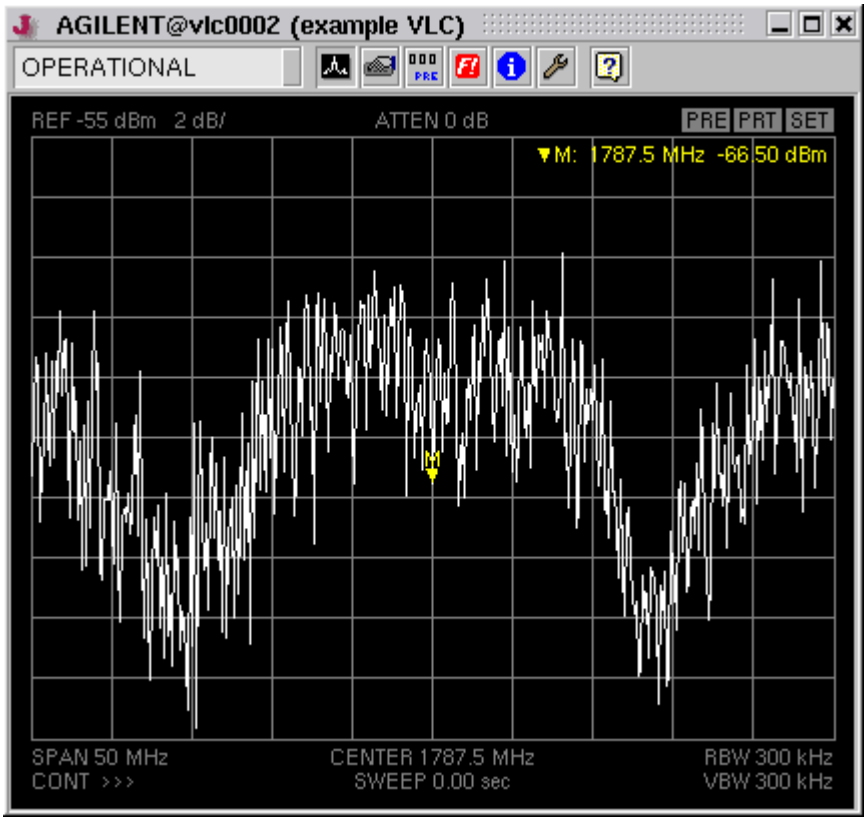
At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the antenna controller.

- *parameter --- description*
- address --- The spectrum analyzer remote protocol does not use a device address. Leave this field empty.
- display --- This configuration parameter switches the local display of the spectrum analyzer on or off. Switching off the display improves the measurement speed of the analyzer in some situations.
- Serial --- The serial line parameters of interface used to drive the spectrum analyzer must be set to the same values set at the device itself (Accessible at the front panel using the 'System' menu). Regardless of the speed, RTS/CTS handshaking must be enabled and a full-wired RS232 cable must be used to the connect the spectrum analyzer to the M&C/VLC.The recommended line speed for the interface depends on the situation where the spectrum analyzer is used. Depending on the speed of the M&C/VLC system and the line speed used to drive the spectrum analyzer there results a maximum sweep rate the system can handle. This sweep rate must not exceed the capacity of the communication line to the NMS or the user interface. The recommended line speeds listed below restrict the sweep rates to values which avoid communication buffer overflows. | *environment* | *line speed* | *max. sweep rate* | | ---- | ---- | ---- | | VLC, connected to the NMS via modem dial up | *9600,E,8,1* | 0.3 / sec | | VLC, connected to the NMS via ISDN dial up or LAN | *19200,E,8,1* | 1 / sec | | M&C system, clients are connected via LAN or ISDN |*38400,E,8,1* | 2 / sec |

See also the note about sweep handling.

The spectrum view

The spectrum view shows the spectrum analyzer's output in a similar format as the local display would do. The display shows the measured spectrum (white) in front of a graticule and a summary of instrument settings.



Clicking into the spectrum display activates the marker. You may drag the mouse with the button held down to see a reticule which follows the spectrum curve. This helps to place the marker manually to peaks. More about marker measurements you find at the next paragraph below.

At the upper left corner of the spectrum view you find three 'buttons' which activate additional function when you click to one of them.

- **PRE** --- Launches a separate window showing the instrument memory page.
- **PRT** --- Opens the printing dialog, lets you print out the actual spectrum display.
- **SET** --- Launches a separate window showing the instrument settings page.

Marker handling

The spectrum view supports two markers. The main marker is that one provided by the instrument itself. The spectrum view colors this marker yellow. You may set the marker manually by clicking with the left mouse button into the spectrum display. While you hold down the mouse button, a reticule is shown which helps you to place the marker precisely. The instrument settings page provides some common marker functions like 'peak search' or 'marker to center'. These function operate on this main marker.

Additionally the spectrum display provides a delta marker function. To use this function, first

place the marker to the location you want to become the reference for the delta measurement. Then set the marker to a second location using the *right* mouse button. This stores the previous marker location as reference (now shown green) to the actual marker location. You may do several delta measurement with the same reference point placing the marker with the right mouse button. Also the peak search and next peak functions work as you might expect. As soon as you place a marker with the left mouse button, the reference point and the delta display gets deleted.

As the marker is based on the instrument's internal marker function, the response to your mouse clicks may be somewhat delayed, specially with a slow communication line. Using the single sweep mode when setting markers improves the performance significantly.

Sweep handling

Viewing the output of a spectrum analyzer at a remote place requires a quite large amount of data to be transferred. Depending on system limitations like the capacity of communication lines this restricts the display update rate to value much lower than the rates you can achieve locally at the instrument.

The spectrum analyzer device driver always operates the instrument in 'single sweep' mode. It manually (i.e. with a remote command) triggers a sweep, when the sweep has finished the trace data is read out and sent to the user interface. The continuous sweep mode selectable at the M&C user interface is implemented in the device driver by repeatedly performing the sequence described above.

Unlike the instrument's local display, the spectrum view shows complete sweeps only. With long sweep times you will find the display frozen until the sweep has completed an the trace data has been transferred to your user interface. With short sweep times, the maximum sweep rate will be limited by the maximum rate the M&C system is capable to handle and to transfer to the user interface rather than by the sweep time itself.

When you change instrument parameters at the M&C user interface, the device driver automatically triggers a new sweep if the driver is in single sweep mode. With a slow VLC and/or a slow communication line you will see a noticeable delay between the parameter change an the screen update.

9.36 Agilis-BUC

This page describes the device driver and the device window for the Agilis integrated BUC / SSPA over SNMP

The driver was tested with

- ALB 129 series compact 80/100W Ku Band BUC in 1:1 redundancy and as standalone unit

The driver was tested with the following SW Releases:

- BUC: 102,109,116
- SSPA: 113,114,116

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- TX --- The transmit parameters
- --- Displays meter readings like output power and BUC specific measurements.
- --- Displays the redundancy settings
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the amplifier.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- powerDisplayMode --- Defines the display of gain or attenuation in the parameter section.
- startup --- Defines the default startup condition for the BUCs transmit state.
- frequency --- Defines the used lo frequency if the unit is equipped with more than one upconverter frequency.

- bucNumber --- Defines the identifier of the BUC in a 1:1 redundancy 1 or 2

9.37 Altec-Puregas-P210

This page describes the device driver and the device window for*Altec-Puregas-P210* waveguide pressurizer and dehydrator via SNMP.

It was tested with P210WLP running on SW: 3.11

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Meter readings.
- --- The faults page.
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the device.

parameter	description
address	The SNMP address specification for the device (details below).
readBackDelay	Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances.
lowPressureThd	Defines the low pressure threshold in psi.
highPressureThd	Defines the high pressure threshold in psi.
highHumidityThd	Defines the high humidity threshold in %.
highRunTimeThd	Defines the high runtime threshold in seconds.
alarmDelay	Defines the alarm delay to be activated or not.
deviceComment	An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

SNMP address specification

The full address consists of the following fields:
`aaa.bbb.ccc.ddd:pppp read-community write-community`

parameter	description
aaa.bbb.ccc.ddd	The IP address of the device in 'dotted quad' notation. This field is mandatory.

parameter	description
pppp	The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
read-community	The SNMP read community name. This must match the read community expected by the device.
write-community	The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses `public` as a default for read and `123456` as write community string.

9.39 Anacom-KuBand-Transceiver

This page describes the device driver and the device window for the Anacom Ku-band transceiver.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device

windows .

- TX --- This page shows transmit part parameters of the device.
- RX --- This page shows receive part parameters of the device. If the device is configured to "TX-ONLY" mode, all parameters of this page remain gray.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Operational parameters

The transceiver's operational parameters contained on the TX/RX device window pages are mostly self explaining.

If you are using a unit with an external SSPA you should consider that the value shown as "measured output power" is a raw, uncalibrated reading which not necessarily has a linear relationship to the true output power of the device. This is is not a limitation of the sat-nms software but an issue with the transceiver itself.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the Anacom transceiver.

parameter	***description***
address	You must set this parameter to the class/id (device address) set at the transceiver. The factory default for the device address id "FFFF", but you are encouraged to customize this value. See below for a description how to change the device address of a transceiver.
txOnly	The device driver has no possibility to detect if the transceiver is a transmit only type or a fully equipped unit. You must set this parameter to match the hardware you are using.
sspa	INTERN tells the device driver that the transceiver to control uses a built in amplifier. EXTERN modifies the behavior for transceiver models using an external SSPA unit.
powerOnDelay	You can force the transceiver to inhibit the transmitted signal for a certain time after power on. The time defined here only becomes effective if you set the next parameter to "ON".
warmUp	This parameter defined if you want to have the carrier forced off after power on for the time defined above. The special value "CANCEL" aborts an actually running warm up period.

parameter	***description***
faultMode	Defines the meaning of the fault relays of the transceiver. If you are using the transceiver together with an Anacom protection switch, set this parameter to "PROTECTION".
Serial	Remember to set the line parameters for the serial interface connected to the transceiver. While the Anacom transceiver's factory preset setting is *1200,N,8,1* , the recommended line setting for the use with the sat-nms software is *9600,N,8,1* . See below how to change this setting at the transceiver.

Communication protocol / Interface type

This device driver requires the Anacom-Packet protocol. It is recommended to use an RS485 (4-wire RS422 mode) interface to control the transceiver. A single transceiver also may be controlled via RS232. If you are using an Anacom protection switch, however, the RS485 interface is mandatory.

Installation

Before you can operate an Anacom transceiver with the sat-nms software, you must prepare the unit to match the interface parameters expected by the software. For this, connect an ASCII terminal (or a PC running a terminal program) to the RS232 port of the transceiver. There comes a special cable with the transceiver for this purpose. Now perform the following steps:

1. Set the terminal line settings to 1200,N,8,1. Hit the "Return" key several times. The transceiver should report it's settings now.
2. Enter " *UTIMER OFF <RETURN>* " to switch off the automatic screen updates.
3. Enter " *R <RETURN>* ". The transceiver will answer something like "*R 123456 FFFF* ". The number 123456 is the unit's serial number, "FFFF" is the address it has actually assigned.
4. Set the new packet address. Enter "*R 123456 0101<RETURN>* ". You should replace 123456 by the serial number the transceiver actually reported. "0101" is the recommended device address for the first unit connected to one single interface. Subsequent units are addressed as "0102", "0103" and so on.
5. Now set the baud rate to 9600: "*BAUDRATE 9600 <RETURN>* ". The transceiver acknowledges this with some strange characters or not at all. This is because the transceivers baud rate no longer matches the rate test at the terminal.
6. Change the terminal's baud rate to 9600. Be sure not to press any key before the baud rate is 9600, the transceiver may fall back to 1200 baud if it does not recognize the keystrokes at 9600 baud.
7. Now finally enter "*SAVE <RETURN>* ". This permanently stores the settings you made. Without the "save" command the transceiver will forget all changes when it is powered off. The transceiver now is prepared for the usage with the satnms software. Remember/note the device address you have set at the device, it must be entered at the software at the maintenance page of the device window as described above.

Setting the EIRP alarm threshold

There is no parameter at the M&C user interface to set the "low EIRP" alarm threshold a the transceiver. The transceiver requires to be set in a special maintenance/programming mode to accept commands which change the alarm thresholds.

First of all, you need the *password* which enables the special programming mode at your transceiver. This password is unique for each transceiver, you have to ask Anacom for the password of your individual unit.

Then, the procedure to set the alarm threshold is slightly different for units with an integrated amplifier and for those with an external SSPA. In principle, there are three steps to:

1. Operate the transceiver at the threshold output power. Apply an input signal and adjust the transceiver gain and/or the drive level to achieve the output power which is just as low that an alarm shall be raised. You should measure the output power using a external power meter or in terms of EIRP by comparing the carrier with other signals you receive from the satellite.
2. Get the detector voltage, the transceiver measures for this output power. You will have the to set the threshold in raw ADC units, so the output power must be read in this way, too.
3. Program the new threshold into the transceiver.

To get the ADC reading, type the command ADC into the "low level command" field at maintenance page of the transceiver's device window. The transceiver should respond with something like **ADC FF 06 23 45 D4 00 00 00 6A .....** Each hexadecimal value in the list is the ADC reading for one measurement point the transceiver monitors. With a unit having an internal amplifier, the **second** value is the one of interest. For units with an external SSPA, note the **8th** value.

Now you can program this ADC value as the low output power threshold into the transceiver. For a transceiver with internal amplifier, type the following sequence of commands into the "low level command" field at maintenance page of the transceiver's device window (replace ?? by the threshold value to set). Wait a few seconds between entering the commands, the normal polling of the device state by the software goes on in background, so the commands are processed quite slow. .pre SPECIAL ART TXOUT ?? FF STORE TABLES EXIT .epre For a unit with external SSPA the command sequency is: .pre SPECIAL PA_LINES ON OFF OFF OFF OFF ON ART PA6 ?? FF STORE TABLES EXIT .epre Due to the fact, that a transceiver with an external SSPA uses the PA6 measurement point of read the detector voltage of the external SSPA, it will raise a "PA power supply" alarm instead of the "low TX power" alarm.

9.40 Anacom-Protection-Switch

This page describes the device driver and the device window for the Anacom 1:1 protection switch.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- This is the main page to control the protection switch. The actual A/B position of the TX- and RX- switch is displayed separately, also the FIXED/AUTO state. Automatic protection is enabled if a switch shows "AUTO". Pressing the A/B buttons forces a switch to this position, reverting it to "FIXED" state. Press "AUTO" to re-enable automatic protection after you have selected the switch position.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the Anacom protection switch.

parameter	*description*
address	You must set this parameter to the class/id (device address) set at the switch. The factory default for the device address id "FFFF", but as the switch shares it's communication interface with two transceivers it is necessary to customize this value. See below for a description how to setup the device addresses of a protection switch an the transceivers connected to it.
Serial	Remember to set the line parameters for the serial interface connected to the protection switch. While the Anacom protection switch' factory preset setting is *38400,N,8,1* , the recommended line setting for the use with the satnms software is *9600,N,8,1* . See below how to change this setting at the unit.

Communication protocol / Interface type

This device driver uses the Anacom-Packet protocol. It requires the switch to be controlled via

an RS485 (4-wire RS422 mode) interface. Operating the switch at the RS232 interface is principally possible, too, but then the transceivers controlled by the switch cannot be operated by the software. The "DIGIPEAT" mode of the switch is not supported.

Installation

Preparing a protection switch and the two transceivers for the usage with the sat-nms software is a little bit tricky, but with the description given below it should be no problem. To understand the following, consider that the protection switch and the two transceivers are controlled via a common RS485/RS422 bus. This requires the units to be set to the same baud rate, but to individual addresses. The description below uses the recommended addresses 0101 for transceiver A, 0102 for transceiver "B" and 0103 for the protection switch.

Preparing the transceivers is no problem, as they have a separate RS232 interface and they usually come with an RS232 cable you can use to program the transceivers before you connect them to the switch.

1. Program the transceiver "A" to the address "0101", as described on thehelp page for this device. Keep the transceiver disconnected from the protection switch for this procedure.
2. Repeat this for transceiver "B", however use the address "0102" fur this unit.
3. Connect the transceivers and the protection switch (i.e. your complete feed / outdoor equipment) and connect it to the M&C computer which already must be prepared to operate a redundant Anacom transceiver pair.
4. With everything connected and powered up, perform the following steps at the M&C user interface:
    - At the maintenance page of the protection switch' device window, set the device address "FFFF" and a line speed of 38400,N,8,1. After some seconds the protection switch should clear it's communication fault.
    - At the field "low level command" enter "*R* " to get the serial number of the switch. It will reply something like "R 123456 FFFF". Now enter " *R 123456 0103* " (you have to replace "123456" by the serial number actually reported by the device). The communication fault appears again.
    - Change the device address to "0103", this makes the communication fault disappear.
    - Enter at the "low level command" entry field "*BAUDRATE 9600* ".
    - Change the BAUDRATE at the M&C computer to 9600, too.
    - Enter the low level command " *DIGIPEAT OFF* ".
    - Finally enter the low level command "*SAVE* " to store the settings in the switch permanently.
5. Finish the setup by entering the device addresses of the transceivers at the maintenance page of their device windows.

The protection switch and the transceivers are now programmed to work with the sat-nms software.

9.41 Andrew-APC100

This page describes the device driver and the device window for the Andrew APC100 antenna controller.

Device window pages

The following table shows which device window pages are available with this individual device

type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The main parameter page displays/controls the antenna pointing. Actual readings and set points are shown in separate fields, so you can see where the antenna is going to while it is moving.The set point parameters are shown with a resolution of 0.1 deg for azimuth/elevation and 1 deg for the polarization. This to make the spin buttons work in a convenient way. You still may enter azimuth/elevation values with a 0.01 deg resolution, the antenna controller accepts this.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the antenna controller.

parameter	***description***
address	The APC100 uses a one character device address in the range 'P' ... '_' (0x50 .. 0x5F). The factory default set by Andrew is 'P'.
polOffset	A non-zero value entered here is **subtracted** from each polarization reading before it is sent to the operator and **added** to each polarization setting before it finally is sent to the device. See the paragraph 'Polarization offset' below.
Serial	Remember to set the line parameters for the serial interface connected to the APC100. The APC100 expects *9600,E,8,1* .

Polarization offset

With the APC100, polarization angles always are positive. A typical range for the polarization setting is 0...180 deg. The sat-nms software however expresses the polarization setting as an offset to the ideal polarization setting for a satellite located at the same longitude as the antenna. These polarization offsets are in the range -90 deg .. +90 deg.

To adapt the APC100 polarization setting/reading to the sat-nms internal standard, the device driver introduces a 'polOffset' configuration parameter. Set this parameter to the polarization reading the APC100 shows while the antenna is positioned to azimuth=180 deg and horizontal polarization.

Software limit ranges

The APC100 provides min/max software limits for all three axes. These limits are set at the APC100 front panel using the "SETUP" menu. The device driver reads the limits from APC100 and forwards them to the sat-nms user interface. An operator will not be able to set antenna

pointing outside the limits programmed into the APC100.

9.43 Antenna-BBU-Connector

The Antenna-BBU-Connector logical device controls three matrix switches to connect the TT&C signals of one antenna to a BBU device. These signals are two telemetry signals from the antenna to the receiver inpüuts and one telecommand signal from the BBU's modulator to the antenna.

The Antenna-BBU-Connector device is logically bound to one antenna. This may be either a movable antenna represented by an Antenna-Management device or a fixed antenna. In the latter case the name of the satellite the antenna is pointed to must be configured in the Antenna-BBU-Connector's setup.

The Antenna-BBU-Connector device permits to connect the antenna to a BBU from a given set of BBUs. The device offers only BBUs from this set, if they are capable to process the satellite this antenna is pointed to. This is either if the name of the satellite reported by the Antenna-Management device matches the satellite name configured for the particular BBU or if the BBU is marked to be a 'spare' one which may be used with any satellite.

Configuration

The configuration of the Antenna-BBU-Connector is defined in a configuration file. This file defines the list of available BBUs, the names of the matrix devices used for switching and the matrix ports the BBUs are connected to. The configuration file is mostly self explaining, here an example:

```
{
  "comment" : [ "Writing the comment this way",

      },
      {
        "useFor" : "TM1",
        "device" : "MTRX-TM1"
      },
      {
        "useFor" : "TM2",
        "device" : "MTRX-TM2"
      }
   ]
}
```

- *antennas:* Contains the list of antennas / Antenna-BBU-Connector devices this configuration file applies to. For each antenna the following parameters must be defined:
  - *device:* The name of the Antenna-BBU-Connector representing this antenna.
  - *satellite:* The name of the satellite the antenna points to. This parameter must be set for fixed antenna, for movable antennas it must be omitted.
  - *satelliteId:* The device name of the Antenna-Management device controlling this movable antenna. For fixed antennas this parameter has to be omitted.
  - *tcPort:* The matrix output delivering the telecommand signal to this antenna.
  - *tm1Port:* The matrix input this antenna feeds its telemetry 1 signal to.
  - *tm2Port:* The matrix input this antenna feeds its telemetry 2 signal to.
- *bbus:* Contains the list of BBUs which may be selected by the Antenna-BBU-Connector. For each BBU the following parameters must be defined:
  - *name:* The name of this BBU as shown in the selection drop down box. The name may be freely defined but should follow the restrictions applying to device names in the satnms software. It should consist of the characters A-Z, a-z, 0-9 and the '-' character only.
  - *satellite:* The name of the satellite this BBU is configured to. BBUs which may be

used with any satellite should have this set to "*".
    - *tcPort:* The matrix input receiving the telecommand signal from this BBU.
    - *tm1Port:* The matrix output delivering the telemetry 1 signal to this BBU.
    - *tm2Port:* The matrix output delivering the telemetry 2 signal to this BBU.
- *matrices:* Contains the list of matrices used to connected antennas and BBUs. This list must contain exactly three objects for the TC, TM1 and TM2 signals.
    - *useFor:* One of "TC", "TM1" or "TM2". Defines for which type of signal this matrix is used.
    - *device:* The device name of the matrix.

Remarks

- Satellite names must match exactly to make the Antenna-BBU-Connector work as expected. The satellite database, satellite names of fixed antennas and the satellite named defined this the BBUs must use exactly the same spelling.
- Matrix ports are to be defined in the way the matrix device driver expects them to identify the input / output parameter and setting. For most satnms matrix drivers this is a 2-digit decimal string with leading zeroes for the numbers 1 .. 9.
- The same matrix may be used to TM1 and TM2 signals. Nevertheless all three entries of the *matrices* list must be specified, defining the same device name for TM1, TM2.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the switch parameter to select a BBU for this antenna.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window if this device there is exactly one configuration parameter to configure the device:

parameter	***description***
confFile	The name of the configuration file defining antennas, BBUs and matrices

Variables defined by this device driver

name	***type***	***flags***	***range***
info.driver	TEXT	R/O	StringRange R/O

name	*type*	*flags*	*range*
info.type	TEXT	R/O	StringRange R/O
info.port	TEXT	R/O	StringRange R/O
info.frame	TEXT	R/O	StringRange R/O
info.indication	TEXT	R/O	StringRange R/O
config.confFile	TEXT	SAVE SETUP	StringRange
position	CHOICE		EnumRange (UNKNOWN)
faults.01	ALARM	R/O	AlarmFlagRange R/O (Configuration)
faults.02	ALARM	R/O	AlarmFlagRange R/O (Switch Combination)

9.44 Antenna-Dummy

This page describes the logical Antenna dummy device driver. It copies the azimuth, elevation and polarisation values to the actual state values.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The antenna pointing window.
- --- The faults page.
- --- The device info page.
- --- The maintenance page.

Variables defined by this device driver

9.45 Antenna-Management

This page describes the device driver and the device window for the Antenna-Management logical device. This device lets you make a motorized antenna follow a satellite based on it's orbit position or ephemeris data. The Antenna-Management device is very similar to the Pointing-Robot device, extends this with a common database which stores the all satellite data like ephemeris data, stored center of box positions and administrative data of the satellite.

If used as a replacement for the legacy Antenna-Pointing device, the Antenna-Management device may be operated in "SIMPLE" mode, which reduces the number of parameter to focus the operation to a simple "mode the antenna to the stored position" for the selected satellite. See "Simple Mode" below for more information about this.

Using the device for recalling data from the database

To use the Antenna-Management device with the database, set the 'tracking data source' parameter to DATABASE. The workflow to track a satellite from the database is as follows:

1. Select the satellite from the 'satellite' list. You may enter partial satellite names to filter the list. There are several sort modes available for the satellite list, the list may be sorted by name, alias, orbit position and other satellite properties.

2. If the Antenna-Management device is setup to control a beacon receiver, select the satellite beacon to use.
3. If the Antenna-Management device is setup to control a TT&C equipment, select the telemetry and telecommand channels to use.
4. If you want to position or track following a tracking table, select the table file name set to use.
5. If you want to position or track following Intelsat I11 ephemerides, select the I11 data set to use.
6. Select the tracking mode to use (see below)
7. Click START to point the antenna to the satellite and to start tracking

The Antenna-Management device offers several tracking modes:

tracking mode	**description**
POINTING	The antenna moves to the pointing stored for the selected satellite in the database and stops.
STEPTRACK	The antenna moves to the pointing stored for the selected satellite in the database and then activates step track at the antenna controller.
MONOPULSE	The antenna moves to the pointing stored for the selected satellite in the database and then activates monopulse tracking at the antenna controller.
TLE	The antenna moves to the pointing calculated from the satellites TLE ephemerides and then tracks the satellite using this data.
I11	The antenna moves to the pointing calculated from the selected I11 ephemerides and then tracks the satellite using this data.
TABLETRACK	The antenna moves to the pointing calculated from the selected tracking table and then tracks the satellite using this data.
TLE-STEP	The antenna moves to the pointing calculated from the satellite's TLE ephemerides in the database and then activates step track at the antenna controller.
I11-STEP	The antenna moves to the pointing calculated from the selected I11 ephemerides in the database and then activates step track at the antenna controller.
TABLE-STEP	The antenna moves to the pointing calculated from the selected tracking table and then activates step track at the antenna controller.
TLE-MONOPULSE	The antenna moves to the pointing calculated from the satellite's TLE ephemerides in the database and then activates monopulse tracking at the antenna controller.

tracking mode	description
I11-MONOPULSE	The antenna moves to the pointing calculated from the selected I11 ephemerides in the database and then activates monopulse tracking at the antenna controller.
TABLE-MONOPULSE	The antenna moves to the pointing calculated from the selected tracking table and then activates monopulse at the antenna controller.

To stop tracking again click the STOP button.

Simple Mode

In SIMPLE mode only the tracking modes POINTING and STEPTRACK are available. The operation sequence differs from that used in FULL mode: First you select the desired tracking mode, then the satellite. The antenna moves to stored pointing for the satellite as soon as the satellite is selected from the list. No additional click to "start" is necessary.

"actual satellite" displays the satellite which recently has been selected for positioning and/or tracking. This persists over a restart of the sat-nms software.

Tracking file handling

The satellite database stores file names for table tracking. These names are assigned to a pair of satellite and antenna. During the satellite selection process the desired file name may be selected using the 'table tracking file name' parameter. The physical file however is **not** read from the database, it is read from the ~/robots directory ad the M&C computer. If the selected file is not found there, the Antenna-Management device complains with an error message.

Controlling the antenna without using the database

To use the TLE / I11 / table Track capabilities of the Antenna-Management device for a satellite which is not stored in the database or has no valid ephemeris data stored there, set the 'tracking data source' parameter to MANUAL and enter the tracking data at the 'Pointing Robot' page. The typical workflow there is to copy the ephemeris data from e.g. a webbrowser window and paste it into the 'ephemeris data' field at this page. The paragraphs below describe the various formats the Antenna-Management device can interpret.

Move the antenna along a satellite position calculated from ephemeris data

You can make the pointing robot follow a satellite position computed from usual ephemeris data sets. The robot recognizes the following data formats:

- **Keplerian elements** --- The robot recognizes and parses keplerian elements in the NASA 2-line format. The two lines of element definition may be prepended by an additional line with the satellite's name. A common source for Keplerian elements in this format is www.celestrak.com . The pointing robot uses the NORAD SDP4 model to predict a satellite's position from this type of data.
- **Intelsat elements** --- Intelsat publish ephemeris data for their communication satellites

at their web site. The data format and the mathematical model for this data is Intelsat proprietary. The pointing robot recognizes this data type as well. You should copy the complete text of the ephemeris data set into the entry field to make the software recognize the data correctly.

Pointing the antenna to the nominal position of a satellite

If a single floating point number is entered to the ephemeris data field, the pointing robot interprets this as a nominal orbit position of the satellite (°E).

Move the antenna along a path given by a table

The pointing robot is capable to move the antenna along a path defined in a text file table. You either may copy the file to the IDU computer by means of FTP and enter the name of file to the ephemeris field or you may enter or cot/paste the table directly to this field. If you do the latter, the size of the table is limited to 32000 characters.

The Pointing-Robot provides a file selection dropdown widget to select files located in the /home/satnms/robot directory on the M&C&VLC server. To use this feature, select the file from the dropdown list and then click "SELECT". This copies the file name into the ephemeris data field and thus selects the file.

Files in the /home/satnms/robot directory which are no longer used may be deleted by selecting the file do delete from the drop down list and clicking DELETE. A file actually in use cannot be deleted, the request is silently ignored.

Polarization calculation

When calculating the antenna pointing from a orbital model or when interpolating the pointing from the table data, the Pointing-Robot also calculates a polarization angle. As each satellite uses its individual polarization offset, the calculated angle is normally for information only. With table tracking, the pointing robot may also command the calculated polarization angle at the antenna.

Setting "apply pol" to CALCED enables this feature. Setting "apply pol" to SAT-DB makes the devices use the polarization angle stored for this satellite in the database.

Tracking table format

The format of the table must be as follows: It contains the data as a three or four column table. Empty lines are ignored, comments starting with a '#' as well. The numbers in the table are parsed as floating point numbers which only may consist of decimal digits, one decimal point and an optional leading '-' if negative. The columns must be separated by an arbitrary number of space or tabulator characters. They have the following meanings:

- 1 --- time stamp The time stamp must be a Julian date with the time of day coded as a fraction of a day. Example: The Julian date for the common base of most computer clocks (1970-01-0100:00:00) is 2440587.5
- 2 --- azimuth angle (degrees, 0.0 == north)
- 3 --- elevation angle (degrees)

Beside this format, the Antenna-Management device accepts MMS files with the following column definitions:

- 1 --- date in the format YY/MM/DD
- 2 --- time in the format HH:MM:SS.sss (UTC)
- 3 --- elevation angle (degrees)
- 4 --- azimuth angle (degrees, 0.0 == north)

File import

The Pointing Robot GUI offers an import function which permits to copy pointing tables from the client computer to the server and thereby convert the file format to that one internally used by the sat-nms software.

Parsing order

If the pointing robot gets entered a new ephemeris data set, it tries to interpret the data in the following way:

1. It checks if the first line of the data specifies an existing file (residing on the IDU computer, therefore the file path should use Unix-style ('/') directory separators if necessary. If there is the specified file, it gets read an interpreted in a way, its file extension suggests: '*.tle' or '*.TLE': NASA 2-line ephemeris data. '*.i11' or '*.I11': Intelsat ephemeris data. Files with other extensions are interpreted as table data as described above.
2. It checks if the data is a valid NASA 2-line data set. A satellite name before the 2-line data is accepted and parsed separately if present.
3. It checks if the data contains valid Intelsat ephemeris data.
4. It checks if the first number in the first line of the data is a valid Julian date in the range 2005 .. 2050. In this case the robot assumes, that the ephemeris data contain a pointing table.
5. Finally, if nothing of the above mentioned formats did match, the robot tries to interpret the first line of the data as the nominal orbit position of the satellite.

If all of the parsing attempts fail, the pointing robot reports the model type to be UNKNOWN. Mostly this happens due to artifacts of previously entered elements which had not been deleted before the new ephemeris data was entered / pasted.

Remote control

The Pointing-Robot may be updated easily with updated pointing tables or ephemeris data by copying such files to the /home/public directory of the M&C system using the SMB file sharing protocol and then commanding the name of this file to the 'elements.input' variable of the Pointing-Robot using one of the M&C system's remote control ports.

ACU fault monitoring

The device can monitor the ACU's summary fault and show it in the device screen. The parameter 'antenna fault detection' may be set to one of the following settings:

- **IGNORE-ACU-FAULT** : The pointing robot ignores ACU faults, does not show them.
- **SHOW-ACU-FAULT** : The pointing robot shows ACU faults, continues to command the antenna controller even if there is an ACU fault.
- **STOP-ON-ACU-FAULT** : The pointing robot stops when it detects a fault of the antenna controller. It must be restarted manually after the ACU fault has been cleared.

Fault flags

In table tracking mode the Pointing-Robot reports two fault conditions regarding the end of table data:

File expired is reported if the end of the table data is reached.

Some hours before (configurable in the device setup) the**File expires soon** fault is reported. The latter fault condition appears as a WARNING by default.

Both fault conditions are reported if the Pointing-Robot is in table tracking mode, even if the tracking is stopped. To clear faults concerning an outdated but unused table, simply clear the "ephemeris data" field.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The main parameter page lets you select a satellite and make the antenna track along the data read from the database for the selected satellite.
- --- The "Pointing Robot" page lets you manually enter ephemeris data for the satellite to track and control the Pointing-Robot integrated into the Antenna-Management directly.
- --- The "Create Robot File" lets you create a table tracking file from ephemeris date read from the database for a given time span for offline use.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the antenna controller.

parameter	***description***
azId	The parameter ID used to control the antenna's azimuth angle.
elId	The parameter ID used to control the antenna's elevation angle.

parameter	*description*
polId	The parameter ID used to control the antenna's polarization angle.

```
    // the connection may be closed meanwhile
```

| azStateId | The parameter ID reporting the antenna's actual azimuth angle. | | elStateId | The parameter ID reporting the antenna's actual elevation angle. | | polStateId | The parameter ID reporting the antenna's actual polarization angle. | | posReachedId | A parameter ID reporting the antenna's 'position reached' state as a boolean parameter. | | motorStopId | The parameter ID used to issue a "motor stop" at the antenna. Leave this empty if the antenna controller does not support this | | motorStopVal | The value to be sent to the parameter ID above in order to stop the motors | | memoryClearId | The parameter ID used to make the antenna clear its tracking memory. Leave this empty if the antenna controller does not support this | | memoryClearVal | The value to be sent to the parameter ID above in order to clear the tracking memory | | stepTrackId | The parameter ID used to switch the antenna controller's step track ON/OFF. Leave this empty if the antenna controller does not support step track | | stepTrackOn | The value to be sent to the parameter ID above in order to enable step track at the antenna controller | | stepTrackOff | The value to be sent to the parameter ID above in order to disable step track at the antenna controller | | targetId | This is a special configuration parameter for using the Antenna-Management device with a Vertex 7200 ACU. This ACU requires a target number to be set in order to run a step track. Set this to '.selectTarget' when controlling a Vertex-7200 ACU. | | monopulseTrackId | The parameter ID used to switch the antenna controller's monopulse tracking ON/OFF. Leave this empty if the antenna controller does not support monopulse tracking | | monopulseTrackOn | The value to be sent to the parameter ID above in order to enable monopulse tracking at the antenna controller | | monopulseTrackOff | The value to be sent to the parameter ID above in order to disable monopulse tracking at the antenna controller | | targetNameId | If set, the Antenna-Management device sends the name and orbit position of the satellite actually tracked to this parameter. This can be used, to display the actually tracked satellite in the device screen of an ACU supporting such a parameter | | beacon.freqId | The parameter ID used to control the beacon receiver's frequency. The value sent is the receive frequency in MHz as the true RF frequency of the signal. Leave this empty if the Antenna-Management device shall not control a beacon receiver | | beacon.attenId | The parameter ID used to control the beacon receiver's attenuation. The parameter value is sent in dB as a floating point value | | beacon.levelId | The parameter ID reporting the beacon level. The parameter addressed by this ID should report the level as a dB value (either absolute or relative) | | beacon.polId | The parameter ID used to control the beacon polarization pane. | | tc.freqId | The parameter ID used to control the telecommand transmit frequency. The value sent is the transmit frequency in MHz as the true RF frequency of the signal. Leave this empty if the Antenna-Management device shall not control a telecommand transmitter | | tc.attenId | The parameter ID used to control the telecommand transmitter attenuation. The parameter value is sent in dB as a floating point value | | tc.polId | The parameter ID used to control the telecommand signal polarization pane. | | tm1.freqId | The parameter ID used to control the primary telemetry receiver's frequency. The value sent is the receive frequency in MHz as the true RF frequency of the signal. Leave this empty if the

Antenna-Management device shall not control a telemetry receiver | | tm1.attenId | The parameter ID used to control the primary telemetry receiver attenuation. The parameter value is sent in dB as a floating point value | | tm1.polId | The parameter ID used to control the primary telemetry receiver polarization pane. | | tm2.freqId | The parameter ID used to control the secondary telemetry receiver's frequency. The value sent is the receive frequency in MHz as the true RF frequency of the signal. Leave this empty if the Antenna-Management device shall not control a telemetry receiver | | tm2.attenId | The parameter ID used to control the secondary telemetry receiver attenuation. The parameter value is sent in dB as a floating point value | | tm2.polId | The parameter ID used to control the secondary telemetry receiver polarization pane. | | reserved | Used by a RX-Channel device to lock the antenna. | | reserved.lo.x | Used by a RX-Channel device to lock one RX band of the antenna. | | reserved.lo.y | Used by a RX-Channel device to lock one RX band of the antenna. | | reserved.hi.x | Used by a RX-Channel device to lock one RX band of the antenna. | | reserved.hi.y | Used by a RX-Channel device to lock one RX band of the antenna. | | beamwidth | The antenna's half 3dB beam width in °. | | diameter | The antenna diameter in m. | | latitude | The antenna's geodetic location (latitude, °N). | | longitude | The antenna's geodetic location (longitude, °E). | | altitude | The antenna's altitude over sea level in m. | | ephemeris.update | If this is set to MANUAL, TLE and I11 data sets are read once from the database when tracking is started. If set to AUTO, TLE and I11 parameter are updated automatically while tracking is active and the data gets updated in the database. |

Database configuration

To give the Antenna-Management device access to the satellite database, the database server IP address as well as user name and password must be defined in the vlc.properties file. The property keys used for this are:

```
db.satlist.host=<IP4-address>
db.satlist.user=<user>
db.satlist.password=<password>
db.satlist.usessl=false
```

If SSL encryption shall be used for the database communication, set the #usessl' key to 'true'. In this case the M&C application's home directory must contain a hidden '.postgresql' directory with the database server's certificate, key and root certificate files. These files can be obtained from the database administrator, they have to be named postgresql.crt, postgresql.key.der and root.crt.

Changes to the vlc.properties file become effective after the next M&C restart.

Remarks

The accuracy of the calculations made by Pointing-Robot depend on the following:

- The geodetic location of the antenna must be known very precisely.
- The antenna's azimuth axis alignment must be precisely perpendicular.
- The clock of the M&C computer must be set to UTC.

9.46 Antenna-Pointing-Fixed

The Antenna-Pointing-Fixed logical device is a variant of theAntenna-Pointing device for non-motorized antennas. Such (small) antennas may view multiple satellites at a time. The Antenna-Pointing-Fixed device permits to define these satellites in the satellites list of the device, thus making the antenna work together with RX-Channel or RX-LineSettings-CDB devices.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the antenna pointing values, the selected satellite name and the orbit position of this satellite. You should use this page if you want to move the antenna to a certain orbit position.
- --- The list of satellite positions. You can select a satellite to move the antenna to with this page and you can maintain the satellite list.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the Antenna-Pointing device work properly.

parameter	***description***
config.reserved.lo.x	
config.reserved.lo.y	
config.reserved.hi.x	
config.reserved.hi.y	These settings give a hint to the RX-LineSettings-CDB devices, that a particular port of the antenna actually is reserved and not available for automatic antenna selection. These settings have no impact to the Antenna-Pointing device itself.
azId	The message ID controlling the antenna's azimuth parameter.
elId	The message ID controlling the antenna's elevation parameter.
polId	The message ID controlling the antenna's polarization parameter.
orbitId	The message ID controlling the antenna's orbit parameter.
polPlaneId	The message ID selecting the antenna's polarization plane. See section "Polarization plane handling" below.

parameter	*description*
longitude	The antenna's longitude (degree east). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.
latitude	The antenna's latitude (degree north). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.
beamwidth	The antenna's half 3dB beamwidth. A satellite is considered a pointed by the antenna, if the azimuth/elevation angles of the antenna match the stored pointing of a satellite within +/- beamwidth.

Operation modes

The Antenna-Pointing device knows three different modes of operation. This is to adapt the behaviour of the device to different types of antennas. By setting the azId, elId, polId and orbitId configuration parameter or leaving them empty you select the proper mode of operation for a particular antenna:

- **Normal 3-axis antenna** : For this antenna type, set the azId, elId and polId configuration parameters to the appropriate parameter identifiers. Leave the orbitId setting empty.In this operation mode, the device will control all three axes of the antenna and it will store complete (az/el/pol) pointing vectors in the satellite table. Only with this operation mode the device is capable to perform *orbit position* to *antenna pointing* calculations.
- **Polamount type antenna** : For this antenna type, only set the azId configuration setting. Leave the other message ID parameters empty.The device will use the azimuth angle to control the antenna's orbit arc setting. This value together with a orbit position angle gets stored in the satellite table.
- **Intelligent mobile SNG antenna** : The third mode of operation is used with car mobile SNG antenna controllers which accept a satellite orbit position angle to point the antenna to this satellite. To enable this mode, leave the azId, elId and polId configuration settings empty and set the orbitId parameter to the appropriate value.The device will act as a simple satellite name to orbit position translator in this mode. Only the orbit position gets stored in the satellite table, the orbit position will be commanded to the antenna controller when a satellite is selected.

Polarization plane handling

The Antenna-Pointing device accepts an operational parameter called 'rxpolplane' (H/V). This parameter may be used to select a certain receive polarization plane by turning the feed (This works with 3-axis antennas only.)

The device translates the commanded polarization angle when forwarding it to the antenna. If horizontal polarization is selected (which is the default if the parameter isn't used), the angle is forwarded as it is. With vertical polarization, the device either adds or subtracts 90 degrees before the value gets forwarded. The device decides if to add or to subtract based on the range of the polarization angle given by antenna controller driver.

If the configuration parameter polPlaneId is set, the device will forward the polarization plane setting to the given device / parameter rather than shifting the polarization angle. The destination may be a switch selecting the polarization plane or a comparable parameter of the antenna controller itself. This "pass-through" mode may be used with all types of antenna controllers, as long as there is a parameter to select the polarization plane.

Remarks

1. To make the antenna move to a satellite already stored in the list, double click to the satellite's entry in the - page.
2. Pressing the right mouse button on a satellite's entry in the list opens a context menu offering all functions to manage the satellite list.
3. When entering a new satellite to the list, first move the antenna to it's calculated position by entering the satellite's orbit position at the - page. Optimize the antenna pointing. Then switch to the - page, add a new entry to the list and update this entry with the current antenna pointing.

Satellite position file

The Antenna-Pointing device stores the satellite positions in a text file in the base directory of the M&C/VLC software. It is named "XXXX.txt" where XXXX is the name of the Antenna-Pointing logical device. The file contains the satellite list as a table of semicolon separated fields. It may be imported by common spread sheet programs this way. The table columns are defined as follows.

1. satellite name
2. orbit position (deg. east)
3. antenna azimuth
4. antenna elevation
5. antenna polarization offset

Be aware, that the numeric values are stored with a decimal dot (##.###), regardless of the default locale of your computer.

9.47 Antenna-Pointing-Hiltron

The Antenna-Pointing-Hiltron logical device is a special version of theAntenna-Pointing device for use with the Hiltron-ACU2 device. Unlike the standard version of the device, this specialized version uses the target memories stored in the ACU as the satellite list rather than maintaining a separate list for this.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the antenna pointing values, the selected satellite name and the orbit position of this satellite. You should use this page if you want to move the antenna to a certain orbit position.
- --- The list of satellite positions. You can select a satellite to move the antenna to with this page and you can store or delete target definitions list.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the Antenna-Pointing device work properly.

parameter	*description*
config.reserved.lo.x	
config.reserved.lo.y	
config.reserved.hi.x	
config.reserved.hi.y	These settings give a hint to the RX-LineSettings-CDB devices, that a particular port of the antenna actually is reserved and not available for automatic antenna selection. These settings have no impact to the Antenna-Pointing device itself.
acuDevice	The device name of the ACU. This must be aHiltron-ACU2 device, the Antenna-Pointing-Hiltron device does not work with other antenna controllers.

parameter	*description*
beamwidth	The antenna's half 3dB beamwidth. A satellite is considered a pointed by the antenna, if the azimuth/elevation angles of the antenna match the stored pointing of a satellite within +/- beamwidth.
diameter	The antenna's dish diameter in meters. This is used by theRX-Channel device when sorting antennas by size in activation based mode.
longitude	The antenna's longitude (degree east). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.
latitude	The antenna's latitude (degree north). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.

Polarization plane handling

The Antenna-Pointing device accepts an operational parameter called 'rxpolplane' (H/V). This parameter may be used to select a certain receive polarization plane by turning the feed .

The device translates the commanded polarization angle when forwarding it to the antenna. If horizontal polarization is selected (which is the default if the parameter isn't used), the angle is forwarded as it is. With vertical polarization, the device either adds or subtracts 90 degrees before the value gets forwarded. The device decides if to add or to subtract based on the range of the polarization angle given by antenna controller driver.

9.49 Antenna-Pointing

The Antenna-Pointing logical device is a 'high level' driver for motor driven antennas. It is used together with a driver for the type of antenna controller used.

While the plain driver for the antenna controller simply supports to set the azimuth/elevation/pol-offset parameters of the antenna, the Antenna-Pointing logical device extends this with additional capabilities:

- It permits to set the antenna pointing by supplying a satellite orbit position. The Antenna-Pointing logical device computes the antenna pointing from the satellite position and sends these values to the low level antenna driver.
- It maintains a list of satellite names, stored together with the orbit position of each satellite and the (manually fine tuned) antenna pointing values for each satellite. The standard user interface for the Antenna-Pointing logical device contains a comfortable tool to handle this list.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the antenna pointing values, the selected satellite name and the orbit position of this satellite. You should use this page if you want to move the antenna to a certain orbit position.
- --- The list of satellite positions. You can select a satellite to move the antenna to with this page and you can maintain the satellite list.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the Antenna-Pointing device work properly.

parameter	***description***
config.reserved.lo.x	
config.reserved.lo.y	
config.reserved.hi.x	
config.reserved.hi.y	These settings give a hint to the RX-LineSettings-CDB devices, that a particular port of the antenna actually is reserved and not available for automatic antenna selection. These settings have no impact to the Antenna-Pointing device itself.
azId	The message ID controlling the antenna's azimuth parameter.

parameter	*description*
elId	The message ID controlling the antenna's elevation parameter.
polId	The message ID controlling the antenna's polarization parameter.
orbitId	The message ID controlling the antenna's orbit parameter.
polPlaneId	The message ID selecting the antenna's polarization plane. See section "Polarization plane handling" below.
longitude	The antenna's longitude (degree east). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.
latitude	The antenna's latitude (degree north). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation.
beamwidth	The antenna's half 3dB beamwidth. A satellite is considered a pointed by the antenna, if the azimuth/elevation angles of the antenna match the stored pointing of a satellite within +/- beamwidth.

Operation modes

The Antenna-Pointing device knows three different modes of operation. This is to adapt the behaviour of the device to different types of antennas. By setting the azId, elId, polId and orbitId configuration parameter or leaving them empty you select the proper mode of operation for a particular antenna:

- **Normal 3-axis antenna** : For this antenna type, set the azId, elId and polId configuration parameters to the appropriate parameter identifiers. Leave the orbitId setting empty.In this operation mode, the device will control all three axes of the antenna and it will store complete (az/el/pol) pointing vectors in the satellite table. Only with this operation mode the device is capable to perform *orbit position* to *antenna pointing* calculations.
- **Polarmount type antenna** : For this antenna type, only set the azId configuration setting. Leave the other message ID parameters empty.The device will use the azimuth angle to control the antenna's orbit arc setting. This value together with a orbit position angle gets stored in the satellite table.
- **Intelligent mobile SNG antenna** : The third mode of operation is used with car mobile SNG antenna controllers which accept a satellite orbit position angle to point the antenna to this satellite. To enable this mode, leave the azId, elId and polId configuration settings empty and set the orbitId parameter to the appropriate value.The device will act as a simple satellite name to orbit position translator in this mode. Only the orbit position gets stored in the satellite table, the orbit position will be commanded to the antenna controller when a satellite is selected.

Polarization plane handling

The Antenna-Pointing device accepts an operational parameter called 'rxpolplane' (H/V). This

parameter may be used to select a certain receive polarization plane by turning the feed (This works with 3-axis antennas only.)

The device translates the commanded polarization angle when forwarding it to the antenna. If horizontal polarization is selected (which is the default if the parameter isn't used), the angle is forwarded as it is. With vertical polarization, the device either adds or subtracts 90 degrees before the value gets forwarded. The device decides if to add or to subtract based on the range of the polarization angle given by antenna controller driver.

If the configuration parameter polPlaneId is set, the device will forward the polarization plane setting to the given device / parameter rather than shifting the polarization angle. The destination may be a switch selecting the polarization plane or a comparable parameter of the antenna controller itself. This "pass-through" mode may be used with all types of antenna controllers, as long as there is a parameter to select the polarization plane.

Remarks

1. To make the antenna move to a satellite already stored in the list, double click to the satellite's entry in the - page.
2. Pressing the right mouse button on a satellite's entry in the list opens a context menu offering all funktions to manage the satellite list.
3. When entering a new satellite to the list, first move the antenna to it's calculated position by entering the satellite's orbit position at the - page. Optimize the antenna pointing. Then switch to the - page, add a new entry to the list and update this entry with the current antenna pointing.

Satellite position file

The Antenna-Pointing device stores the satellite positions in a text file in the base directory of the M&C/VLC software. It is named "XXXX.txt" where XXXX is the name of the Antenna-Pointing logical device. The file contains the satellite list as a table of semicolon separated fields. It may be imported by common spread sheet programs this way. The table columns are defined as follows.

1. satellite name
2. orbit position (deg. east)
3. antenna azimuth
4. antenna elevation
5. antenna polarization offset Be aware, that the numeric values are stored with a decimal dot (##.###), regardless of the default locale of your computer.

9.50 Antenna-Proxy

The Antenna-Proxy logical device translates parameters between different antenna controllers to the parameters from the Antenna-Pointing device.

This is useful if the antenna controller includes already a satellite list (like the SatService-ACU-ODM) but you need the standard interface of the Antenna-Pointing device for other logical devices like the RX-ChannelSelect devices.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- This page shows the selection state
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to interconnect the Level-Set device to the devices it monitors and controls.

parameter	*description*
satId	The message ID for the satellite name
azId	The message ID for the azimuth reading.
elId	The message ID for the elevation reading
polId	The message ID for the polarization reading

9.51 Antenna-Tracking

Please note, the Antenna-Tracking device is no longer maintained andshould not be used for new M&C installations.

The Antenna-Tracking logical device is a 'high level' driver for motor driven antennas. It is used together with a driver for the type of antenna controller used. To operate the device in step track modes, also a beacon receiver is required. The Antenna-Tracking device provides three mayor tracking modes:

- **STEP** --- In plain step track mode, the device performs small test steps with the antenna in regular intervals to see if the receive level becomes better or worse for another antenna position. With the knowledge of the antenna pattern's shape, the tracking engine computes an optimized position from measurements taken at the old position and at the new one. Many parameters such as the step size, averaging times and the overall repetition interval are configurable by the operator.
- **ADAPTIVE** --- The adaptive tracking mode works much like the plain step track, however

the tracking engine in background computes a mathematical model of the antenna motions from the step track results. After a tracking step the antenna is moved to the position computed from this model rather than to the measured maximum. This significantly smooths the path at which the antenna follows the satellite. Another great advantage of this mode is that the antenna follows the computed model even if the beacon reception fails. With the plain step track mode, the antenna would freeze in this case until the satellite beacon appears again.

- **PROGRAM** --- With the third tracking mode called program track, the antenna follows a position computed from the satellite's ephemeris data. The tracking engine accepts Keplerian elements in NASA 2-line format or the proprietary Intelsat ephemeris data format for this. For this tracking mode, no beacon reception is required, however the ephemeris data sets must be updated every few days.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Basic tracking parametersThe primary page contains the basic tracking parameters like the nominal antenna position or the mayor tracking mode. This page also gives access to the logging and analysis tools built into the tracking device. The most important parameters are explained below:**satellite name:** This ist the name of the satellite as it appears in the list of stored targets. When you read in ephemeris data which contains a satellite name, the latter gets copied into this field. You may however enter any other name.**nominal orbit:** With this parameter the satellite's nominal orbit position is specified. There are two applications for the nominal orbit value in the software: The tracking device is capable to evaluate the antenna pointing angles for the orbit position, you may move the antenna to the resulting position in order to find a new satellite quickly. Also the orbit value is used to identify and sort satellites in the target list.The nominal orbit position has to be entered as 'deg. east' To specify a satellite at 10° West, either enter -10.0 or 350.0, the software accepts both notations.**tracking mode:** With this parameter you select the major tracking mode. Available modes are:
  - STEP --- Plain step track mode.
  - ADAPTIVE --- Step track with mathematical model assistance / backup.
  - PROGRAM --- Program track following given ephemeris data.**interval:** Defines the overall tracking interval. The tracking device performs it's steps not faster than defined with this parameter. If an optimization step takes longer than this interval, this is not treated an a fault. The tracking device will start the next step immediately after the first one has finished. Set this value to 0 in order to force the tracking to operate at a maximum rate.The effective duration of one optimization step primarily depends on the integration times and delays defined with the advanced step track parameters. But also the fluctuation of the beacon level reading has an impact to the duration of a tracking step. If the standard variation of the readings will exceed a configurable threshold, the tracking algorithm will try to repeat the measurement several times.**az/el nominal:** These fields define the nominal position of the antenna for this satellite. The nominal position is the center

of the box in which the antenna tracks the satellite. The size of this box is set on the 'advanced tracking parameters' page described below. The nominal position also is that one the antenna moves to, if the satellite's tracking settings get recalled from a preset memory.Changing one of the nominal position values while the tracking mode is 'OFF' immediately moves the antenna to the given position. With tracking enabled, changing a nominal position value does not move the antenna, only the box limits are shifted accordingly.**polarization:** The polarization value directly controls the antenna's polarization offset motor (if available). None of the tracking algorithms changes this value, in must be optimized manually when a satellite is going to be tracked the first time.**beacon frequency:** This parameter controls the beacon receiver's receive frequency. The true RF receive frequency value is required, not an L-band frequency. It is necessary to enter this value even if the beacon receiver is not controlled by the tracking M&C system. This is because the tracking engine uses the beacon frequency to compute the tracking step sizes.**beacon pol.:** With beacon receivers which are capable to switch the input polarization, this parameter permits to select the polarization plane of the beacon to receive.**Y/T PLOT:** Clicking to the 'Y/T PLOT' button opens a window which shows a diagram of the antenna movement and the beacon level over the time. If you leave this window opened, it gets updated with each tracking step the antenna makes. See the paragraph 'built in analysis tools' below for further information.**X/Y PLOT:** Clicking to the 'X/Y PLOT' button opens a window which shows a diagram of the antenna movement in both axes. If you leave this window opened, it gets updated with each tracking step the antenna makes. See the paragraph 'built in analysis tools' below for further information.**STEP LOG:** Clicking to the 'STEP LOG' button opens a window where the program shows a live report what the tracking engine actually is doing. The log in this window is cleared with each new tracking step. If 'Y/T PLOT' diagram shows many unsuccessful tracking steps, watching the 'STEP LOG' reports may give an explanation why the tracking engine discards so many steps.**RESET POS:** Moves the antenna back to it's nominal position**RESET MEM:** Clears the tracking memory used by the ADAPTIVE tracking mode.**orbital model:** Displays the type and age of the orbital model used by the PROGRAM tracking mode. While in ADAPTIVE tracking mode 'ADAPTIVE' is displayed.**operation state:** Reports the actual operation state of the tracking engine. This mainly reflects the major tracking mode, but also contains some additional information, e.g. which type of ADAPTIVE model the tracking engine actually uses.**tracking step:** Reports the tracking step which recently has been done. This exactly matches the last line of the 'STEP LOG' display.**tracking offset:** These fields report the actual offset of the antenna pointing from the nominal position.**beacon level:** Displays the beacon level as actually read from the beacon receiver.

- --- Satellite listThe satellite list page permits to store tracking settings in a target memory pool which is unique to this instance of the Antenna-Tracking device. This is unlike the standard device preset function if the sat-nms software which stores device settings for all instances of one device type at a central place. The following functions are provided by this page:**Save actual satellite:** Clicking to this button stores the actual tracking parameters together with the nominal antenna pointing into a data file named after the actual satellite name followed by the nominal orbit position. If a file of this name

already exists, it gets replaced.**Delete seleted entry** Deletes the selected (yellow colored) target memory file.**Load selected parameters** Loads all tracking parameters except the nominal antenna pointing from the selected target memory. This is intended to be used to copy the tracking settings from an already known satellite to a new one, which actually is being set up.**Track selected satellite** Loads all settings including the nominal antenna pointing and the tracking mode. Moves the antenna to the nominal pointing position and starts the selected tracking mode there.

- --- Orbital modelAt this page you may define an orbital model for the satellite which is used with the PROGRAM tracking mode. The orbital model also may be used to find a satellite more precisely than by it's nominal orbital position.The tracking engine accepts either Keplerian elements in NASA 2-line format or Intelsat ephemeris data. The software automatically recognized the data format and chooses the appropriate orbital model. A common source for actual Keplerian ephemeris data is www.celetrak.com , weekly updated Intelsat orbital data may be found on the Intelsat web site.The easiest way to enter the orbital data to the tracking system is by copy & paste from the source web site. Clear the orbital data field, mark the desired orbital data in the web browser window and copy it into the orbital data entry field (use CTRL-C/CTRL-V on Windows based PC, the middle mouse button on Linux boxes like the sat-nms ACU indoor unit. For Intelsat data, copy the whole web page which shows the ephemeris data set. For Keplerian data copying the two lines containing the element data is required. When using data from Celestrak, you optionally may copy also the comment line above the element data, the satellite name will be adapted automatically in this case.Once you entered / copied the orbital data and change the input focus to another field, the software analyzed the data and updates the fields at the top of the page. The 'recognized orbital model' shows the type and age of the interpreted ephemeris data. The 'satellite name' and 'nominal orbit' are updated accordingly, if this information is present in the entered data. If you select the PROGRAM tracking mode on the primary parameter page, the antenna follows the position of the satellite as computed from the ephemeris data.Using the buttons below the orbital data entry field you may compute the actual antenna pointing either from the entered ephememeris data or from the satellite's nominal orbit position. Clicking to the large button at the bottom move the antenna to the computed position. This function is intended to be used to find a new satellite quickly. If there is no orbital data available for the satellite you search, you may enter it's nominal orbit position directly and compute the antenna pointing from this.The accuracy of the calculated antenna positions heavily depends on the antenna pointing calibration and on the accuracy of the antenna's geodetic location as defined with the configuration parameters.

- --- Advanced step track parametersThis page contains a number of parameter which are used to tune the tracking algorithm. Most of these parameters affect the STEP and ADAPTIVE tracking modes as well.**step size:** This parameter controls the sizes of the search steps the tracking engine performs in the STEP and ADAPTIVE modes. With the step size set to 100%, the elevation test step is one half of the antenna's 1dB bandwidth. The azimuth step size is computed the same way, but divided by *cos(elevation)* to deskew look angle to the satellite. The antenna's beamwidth (approximately) is computed from the beacon frequency and the antenna diameter. A good initial value for the step size is 60%.**settling time:** The settling time is the time the tracking engine

waits after it issued an antenna pointing command until it takes the first sample of the beacon level. Specially with small steps of the antenna position, the tracking engine has no real feedback when the antenna has reached it's final position. This delay time is used to ensure that the antenna pointing command has been executes and the beacon level has settled.**step mode:** In STEP mode, this parameter controls how the tracking engine selects the direction of a search step. With the SLOW step mode, search steps alternately are made in the one or the other direction. This step mode gives good results with satellites that move only a small amount. With the FAST step mode, each search step is made in the same direction of the last successful optimization step. With any unsuccessful step the direction changes. This mode is recommended to track inclined orbit satellites, because the tracking does not perform search steps against the satellite movement in the majority of cases. In the ADAPTIVE tracking mode, the tracking engine observes the step mode selection only as long as it cannot compute a usable model from the records steptrack data. Later it uses the the modeled antenna pointing to decide where to go for a search step.**max optimization:** The step track algorithm uses the measured beacon levels before a search step and after it together with some knowledge about the shape of the antenna beam to compute the peak location. Unexpected variations of the beacon level may disturb the measurement and may result to a wrong peak evaluation. To minimize the impact of this to the antenna pointing, the tracking algorithm limits the amount of an optimization step to this value. Setting this parameter to 0% forces the tracking engine to limit the peak position to a window between the antenna positions before and after the search step. Increasing the 'max optimization' parameter widens this window at both edges with the actual search step size multiplied by the 'max optimization' value.With the ADAPTIVE tracking mode this parameter is used, too. Here however it acts as a fault threshold: If a peak is outside, is is marked as invalid and not included to the tracking model computation.**az/el search step:** These fields show the actual search step sizes as absolute angles for you orientation. The fields get updated each time you change the 'step size' parameter.**az/el window:** These parameters define a rectangular window around the nominal antenna position. The tracking engine limits the optimization movements to this window.**beacon averaging time:** This parameter defines the time, while samples read from the beacon receiver get averaged to achieve one beacon level value. Recommended values are between 15 and 30 seconds, if the beacon receiver itself performs an effective averaging/smoothing of the level reading, shorter values may be possible.**max standard deviation:** While the program averages the beacon level readings, it also computes the standard deviation of the reading as a measure of the (short term) stability of readings. If the standard deviation exceeds this limit, the measurement is discarded.**max signal drift:** Before performing a search step, the tracking algorithm requires two beacon measurement series to differ not more than the value defined here. Otherwise the beacon level is assumed to drift, the search step is postponed or canceled.**max drop in search step:** If with a search step the beacon level drops more than the value set here, the antenna moves back to the previous or predicted position, no peak evaluation is done.**min beacon level:** If the measured beacon level falls below this value, a beacon level fault is risen and the measurement is marked as invalid. With the STEP tracking mode no tracking is performed until the beacon level is above the threshold again. In ADAPTIVE mode, the tracking engine tracks the satellite following the mathematical model made from the step track peaks.

- --- Faults and fault mask**Beacon receiver:** The beacon receiver device states a fault. This may be a hardware fault or a loss of signal. It is recommended to switch of any level threshold monitoring at the beacon receiver and let the tracking device monitor the beacon level. The tracking device applies threshold monitoring only during the measurement phases, signal dropouts during the antenna movement phases are ignored.**Beacon level:** The measured beacon level is below the threshold set at the advanced step track parameters page.**AZ/EL window limit:** The recent step track peak found is outside the window limits set at the advanced step track parameters page. The antenna has been moved to the window limit rather than to the peak position. The fault stays active until the next tracking step.**Antenna:** The antenna positioning controller states a fault. This may be a motor failure, limit switch or another specific antenna fault.**Search step size:** The tracking engine is not capable to compute a valid tracking step size from the given data. This happen if either the antenna diameter (a setup parameter) or the beacon frequency is not set properly. The fault stays active until the missing value is set.**AZ/EL Model match:** In ADAPTIVE tracking mode, a tracking step found a peak which considered to be invalid at it is too far away from the position computed by the model. The fault stays active until the next tracking step.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the Antenna-Tracking device work properly.

parameter	***description***
config.azimuthId	Enter here the parameter ID of the azimuth target value the tracking unit shall use. Example: 'ODU.azimuth'
config.stateAzId	Enter here the parameter ID of the azimuth read out value the tracking unit shall use. Example: 'ODU.state.az'
config.elevationId	Enter here the parameter ID of the elevation target value the tracking unit shall use. Example: 'ODU.elevation'
config.stateElId	Enter here the parameter ID of the elevation read out value the tracking unit shall use. Example: 'ODU.state.el'
config.polarizationId	Enter here the parameter ID of the polarization offset target value the tracking unit shall use. The tracking unit does no polarization, however a fixed polarization offset value is stored together with each target. Example: 'ODU.polarization'
config.antennaFaultId	Enter here the parameter ID of the antenna fault, the tracking unit shall monitor.

parameter	***description***
config.bcrxFreqId	Enter here the parameter ID of the beacon receiver frequency setting. The tracking unit sends the receive frequency stored with a target to this parameter (RF frequency, not L-band). Leave this field empty, if the beacon receiver frequency cannot be controlled through the sat-nms software. Please note, that in the tracking unit the beacon frequency must be set to the correct value even if it is not passed to the beacon receiver. This is because the tracing unit computes the step track search sizes from the beacon frequency.
config.bcrxLevelId	Enter here the parameter ID of the beacon receiver level reading. The value is expected to be a receive level in dBm or a C/N value [dB]. To read the analog output value of a tracking receiver, you need an external device which reads this voltage and converts the readint to dBm. The sat-nms Antenna Control Unit ODM is capable to do this.
config.bcrxFTrackId	If you are using a sat-nms L-band beacon receiver together with this tracking device, enter 'BCRX.ftrack.fast' here, replace BCRX by the device name of the beacon receiver. This tells the tracking engine to perform a synchronous frequency tracking step on the beacon receiver before each antenna tracking step.
config.bcrxFaultId	Enter here the parameter ID of the beacon receiver fault, the tracking unit shall monitor.
config.xDiameter	This parameter tells the tracking device the width of the antenna dish. The tracking device computes the azimuth tracking step size from this parameter and the beacon frequency value.
config.yDiameter	This parameter tells the tracking device the height of the antenna dish. The tracking device computes the elevation tracking step size from this parameter and the beacon frequency value.
longitude	The antenna's longitude (degree east). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation
latitude	The antenna's latitude (degree north). Provide this value with an accuracy of 0.01° to ensure a precise orbit to pointing calculation
altitude	The antenna's altitude over sea. Provide this value with an accuracy of 10 meters to ensure a precise orbit to pointing calculation

Built in analysis tools

The Antenna-Tracking device is capable to show two different types of diagrams which support

you to monitor and optimize the tracking behaviour.

The first diagram tool is the X/Y display of the antenna movements. This display works completely autoscaled, it shows one green dot for each antenna position the tracking memorizes (usually the recent 48 hours). The actual antenna pointing is marked with a slightly larger yellow dot. After at least 24 hours of continuous operation, the antenna position dots give the curve of the daily movement of the satellite, from the antenna's angle of look. With a mouse click to the diagram area, the display cas be switched into a Y/T diagram showing the recent 48 hours. This condensed display of the azimuth, elevation and beacon level variations over 48 hours is meant as an overview display. A second mouse click switches back to the previous view.

The separate Y/T display window gives more detailed information about what the tracking engine did during the recorded 48 hours. It provides variable scales, and permits to display additional information. The display shows either the azimuth or the elevation pointing found at the beginning of each each tracking step together with the beacon level measured at this time. The following additional information may be included to the diagram:

- --- If this toolbar button is pressed, the diagram shows the search step and the beacon level change resulting from this as a dimmed peak at the left edge of each data point. You can easily monitor the signal degradation which is caused temporarily by the tracking search steps with this function enabled.
- --- If this toolbar button is pressed, the diagram includes the evaluated peak positions. In STEP track mode, this actually is the location where the antenna gets moved to. In ADAPTIVE tracking mode, the antenna moves to the location resulting from the mathematical model which is computed from the step track peaks. In the latter case, the peak positions may be interpreted as the actual difference between the modeled pointing and the peak position.

Recommended beacon receiver settings

Below some recommended settings for the sat-nms L-band beacon receiver for the use with the tracking device are listed. These settings have proved to work satisfactory in most cases. If you are using a third party beacon receiver, use analogous values a starting point.

- Measurement bandwidth --- 30kHz
- Post detector filter --- 0.5 Hz
- Frequency tracking --- OFF (the tracking device switches this ON/OFF automatically with a sat-nms L-band beacon receiver)

9.52 Antenna-Wind-Protection

The Antenna-Wind-Protection logical device protects an antenna from high wind speeds by either stopping all antenna movement and fastening the brakes or by moving the antenna elevation up to a stow position where the wind load to the antenna's construction is minimized.

The device monitors two wind speeds, each as a momentary and an averaged value. The wind

speed measurement values are typically provided by a Dual-Wind-Speed logical device, but other sources are configurable. It takes the maximum value from the two wind speed meters individually for the momentary and the average reading. These max values are compared to configurable limits in order to evaluate an action to perform. The device provides two protection mechanisms, "stop" and "stow", which are working independently from each other.

Antenna Stop procedure

The device compares the momentary and the averaged wind speed to a pair of limit values. If either the momentary or the averaged value exceeds its limit, the antenna gets stopped by execution of the "stop" macro. This macro should contain all antenna settings necessary to lock the antenna safely in its actual position (switch off tracking, fasten brakes).

Antenna Stow procedure

In parallel to the procedure described above, the device compares the momentary and the averaged wind speed to another pair of limit values. If either the momentary or the averaged value exceeds its limit, the "stow" procedure gets triggered. The stow procedure consists of the following steps:

1. The device issues a warning and wait for a configurable time (default is 30 seconds). During this time the procedure can be aborted without manipulating the antenna's state.
2. After the initial delay has elapsed, the device executes the "pre-stow" macro. This macro should contain any antenna settings which are necessary to prepare the antenna to be moved to its stow position.
3. After the execution of the pre-stow macro has finished, the device commands the antenna to move the elevation to its stow position.
4. Now the antenna waits until the elevation reading matches the commanded stow angle within 0.05 degrees.
5. When the stow position is reached, the devices executes the "post-stow" macro. This macro should contain all antenna settings which are required to lock the antenna in the stow position.
6. After the macro execution has finished, the device turns into the STOWED state.

The procedure may be aborted at any time by clicking the "ABORT" button, but this does not stop running macros nor does it stop the elevation to move to the stow position if this already has been commanded. Clicking "ABORT" simply turns the device into the ABORTED state.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows and controls the state of the protection procedures.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the Antenna-Wind-Protection device.

parameter	***description***
config.speed.1.act.id	The parameter ID of the wind speed 1 actual / momentary value.
config.speed.2.act.id	The parameter ID of the wind speed 2 actual / momentary value.
config.speed.1.avg.id	The parameter ID of the wind speed 1 average value.
config.speed.2.avg.id	The parameter ID of the wind speed 2 average value.
config.elevation.state.id	The parameter ID of the antenna's elevation angle reading.
config.elevation.cmd.id	The parameter ID of the antenna's elevation target value setting.
config.elevation.stow	The elevation angle to command when stowing the antenna.
config.stopMacro	The name of the macro to execute in order to stop the antenna.
config.preStowMacro	The name of the macro to execute before stowing the antenna.
config.postStowMacro	The name of the macro to execute after stowing the antenna.
config.act.stopLimit	If the higher value of the actual wind speeds exceeds this value, the antenna gets stopped.
config.act.stowLimit	If the higher value of the actual wind speeds exceeds this value, the antenna gets stowed.
config.avg.stopLimit	If the higher value of the averaged wind speeds exceeds this value, the antenna gets stopped.
config.avg.stowLimit	If the higher value of the averaged wind speeds exceeds this value, the antenna gets stowed.
config.stowDelay	The time to wait until the stowing procedure actually starts (seconds).

Setting up the device

The Antenna-Wind-Protection device depends on a number of macros you have to supply in order to make the device work properly. Macros have been chosen for this because each type of antenna controller requires different settings and commands to perform the actions before and after the stow procedure or to stop the antenna safely.

The device suggests names for these macros which contain the name of the Antenna-Wind-Protection device and a suffix describing what the macro shall do. You may use these names or names of your choice. However, all three macros must exist with the names set at the device's configuration parameters or the device will signal a fault.

Manual release procedure

If the device stopped or stowed the antenna due to high wind speed, the operator has to restore the antenna's state and the state of the Antenna-Wind-Protection device to normal operation conditions. The procedure ist almost the same for stop and stow conditions. It also applies when an antenna stow has been aborted and the pre-stow macro already has been executed.

1. Wait until the wind has calmed down to speeds the antenna mount han handle.
2. Point the antenna back to the satellite, activate tracking (if applicable).
3. Finally click "RELEASE" at the Antenna-Wind-Protection device to re-activate the wind protection procedures.

9.53 AntwerpSpace-G3-Demod

Device driver for the 3rd generation AntwerpSpace Omnisat G3 Demodulator (IPC based solution).

It can be used to control one demodulator instance in a Ominsat G3. If more than one demodulator is used inside a chassis, additional instances of this driver can be added under the same device thread. Assigning the dedicated demodulator can be done via device setup *config.boardId* . Additionally mixed board combinations can be covered by adding an Modulator HDRM AntwerpSpace-G3-Mod to the same thread/chassis.

This driver interfaces via REST HTTP to the demodulator web server it requires expert privileges to be able to do a counter reset / carrier reaquisition. Beside that the driver only contains HDRD operational access parameters. It does not contain parameters for: CCSDS-FEP (configurational) and DVBS-FEP (configurational and monitoring).

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The HDRD monitoring parameters
- --- The HDRD configuration parameters
- --- The CCSDS-FEP monitoring parameters
- --- Load units mission/configuration presets
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	***description***
address	The REST HTTP specification for the device. The full address specification consists of the following fields: *aaa.bbb.ccc.ddd:pppp username password* *aaa.bbb.ccc.ddd* The IP address of the device to control in 'dotted quad' notation. This field is mandatory. *pppp* The IP port number where the device accepts http requests. The port number may be omitted, the driver uses the standard port 80 in this case. **username password* The Web access username and password for expert access: (Default: **og3expert** and **og3expertpwd**)
boardId	Defines the board index where the HDRD demodulator is installed.

HTTP session reuse

Multiple devices located in the same frame (using the same IP address) can be configured to share the same HTTP session. For this enter the IP address and login credentials at the 'address' config parameter of the first device. For all other devices enter the name of the first device instead. These devices then reuse the HTTP session / connection of the first device. This has several advantadges:

- There is only one HTTP session for all devices and only one login at the physical device. this is specialy helpful for devices which limit the number of session which are opened in parallel like the Haivision-SRT-Gateway.
- HTTP keep-alive will be enabled for all HTTP requests to the device. This reduces the number of TCP sockets opened and (specially with HTTPS) significantly improves performance.

9.54 AntwerpSpace-G3-Mod

Device driver for the 3rd generation AntwerpSpace Omnisat G3 Modulator (IPC based solution).

It can be used to control one modulator instance in a Ominsat G3. If more than one modulator is used inside a chassis, additional instances of this driver can be added under the same device thread. Assigning the dedicated modulator can be done via device setup *config.boardId* . Additionally mixed board combinations can be covered by adding AntwerpSpace-G3-Demod) to the same thread/chassis.

This driver interfaces via REST HTTP to the modulator web server it requires only operator privileges.The driver only contains HDRM operational access parameters. It dows not contain parameters for: CCDS-FEP and DVBS-FEP.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- The HDRM monitoring parameters
- --- The HDRM configuration parameters
- --- Load units mission/configuration presets
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	*description*

parameter	*description*
address	The REST HTTP specification for the device. The full address specification consists of the following fields: *aaa.bbb.ccc.ddd:pppp username password* *aaa.bbb.ccc.ddd* The IP address of the device to control in 'dotted quad' notation. This field is mandatory. *pppp* The IP port number where the device accepts http requests. The port number may be omitted, the driver uses the standard port 80 in this case. *username password* The Web access username for operational access: (Default: **operator**)
boardId	Defines the board index where the HDRD demodulator is installed.

HTTP session reuse

Multiple devices located in the same frame (using the same IP address) can be configured to share the same HTTP session. For this enter the IP address and login credentials at the 'address' config parameter of the first device. For all other devices enter the name of the first device instead. These devices then reuse the HTTP session / connection of the first device. This has several advantadges:

- There is only one HTTP session for all devices and only one login at the physical device. this is specialy helpful for devices which limit the number of session which are opened in parallel like the Haivision-SRT-Gateway.
- HTTP keep-alive will be enabled for all HTTP requests to the device. This reduces the number of TCP sockets opened and (specially with HTTPS) significantly improves performance.

9.55 AntwerpSpace-IBB-Modem

This page describes the *Antwerpspace-IBB-Modem* device driver and its device window. The *Antwerpspace-IBB-Modem* device driver uses the CCCOM protocol and reads the following tables: version and system table, the modulator Table (component #40), the subcarrier modulator table (component #30), the suppressed carrier modulator table #1 (component #36), the demodulator table (component #4), the psk subcarrier demodulator table (component #8), suppressed carrier demodulator table (component #12), the telemetry table (component #16). Beside that it allows setting a small selection of parameters from this tables, start and stop of the modules

It was developed base on ICD v4.07 from 2021/12/15

The IBB requires two separate IP connection for monitoring and commanding the device. The device driver establishes the connection to the monitoring port (usually 5000) by terminal server like TTY connection. This connection is permanently active. Address and port are set in the vlc.setup configuration file as for a terminal server serial port.
The default Monitoring Port is 5000 It allows up to 5 connections at a time.
The default Command Port is 5001. It allows only one connection at a time.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Modulator settings and status
- --- ^Demodulator 1 settings and status
- --- Telemetry settings and status
- --- Baseband Session and Diversity calibration
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at

this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the device.

parameter	***description***
address	No address required
cmdPort	Defines the command port. Standard port is 5001
mod.defaultState	Defines the the default modulation state when loading a new configuration (ON/OFF)
mod.defaultLoop	Deines the default IF loop state (INTERNAL/EXTERNAL). If set to internal loop, the modulator output is directly connected (at IF level) to all the inputs.

9.56 Apollo-Switch

This page describes the device driver and the device window for the Apollo Microwave

Waveguide Switching and HPA Protection system tested with 3 waveguide switches and 3+1 HPA redundancy

Device window pages

The following table shows which device window pages are available with this individual device type.

- --- The operational parameters

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

parameter	***description***
address	The device address (decimal) as set at the device's front panel.
Serial	Remember to set the line parameters for the serial interface

Variables defined by this device driver

9.57 Arithmetic

The Arithmetic logical device combines two numeric values by adding, subtracting, multiplying or dividing them. Both input terms may either be constant values or the actual value of any numeric parameter of another device.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Shows the actual input output values of the device.
- --- The device info page.
- --- The maintenance page. The configuration parameters from this page are described below.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to interconnect the Arithmetic device with the devices that deliver the input signals and to configure the device's performance.

parameter	*description*
arithmeticType	With this parameter you define the arithmetic operation the device shall perform.
comment	The comment is displayed with the device's output value at the device window. You may set it to describe the purpose of the computation.

parameter	***description***
input-A.Id	Enter the ID of the parameter the device shall use as input A here. Leave the field empty if input A shall be set to a constant value
input-A.constant	Enter the constant value for input A here. Leave the field empty if input A shall follow another parameter.
input-A.comment	The input A comment is displayed above value at the device window.
input-B.Id	Enter the ID of the parameter the device shall use as input B here. Leave the field empty if input B shall be set to a constant value
input-B.constant	Enter the constant value for input B here. Leave the field empty if input B shall follow another parameter.
input-B.comment	The input B comment is displayed above value at the device window.

Remarks

- The device uses A as the first, B as the second operand. Thus SUB calculates *a-b* , DIV calculates *a/b* .
- If a division by zero error occurs, the device does not claim this and leaves the output value unchanged.
- *Never* use the device's output parameter as one of the inputs. This feed-back will cause an endless recursion which in fact will eat up all available CPU power and memory.
- The device 'learns' the number of fraction digits to display at the main page from the connected parameter's definition. The number format of input A also is used to display the output value. If you re-configure an input from constant to parameter-ID and vice versa you may need to restart the software in order to get the number format displayed correctly.
- Connecting the device to non-numeric parameters (textual parameters, multiple choice parameters) will lead to unpredictable results.

Variables defined by this device driver

output	FLOAT	R/O	DoubleRange R/O (0.000 .. 0.000)
a	FLOAT	R/O	DoubleRange R/O (0.000 .. 0.000)
b	FLOAT	R/O	DoubleRange R/O (0.000 .. 0.000)

9.58 Astro-EdgeStreamer

This page describes the device driver and the device window for the Astro Edge Streamer U148-X device.

It supports four RF SAT inputs and can decode 16 channels in total. Each channel can utilise one specific RF input of the existing four and have its own frequency, symbol-/code rate rolloff, modulation etc. with the ability to check the running services and stream it

Each U100 19'' rack frame supports three U148-X devices with separate MGMT IP-Address, RF inputs and Ethernet outputs. The driver treats each one is treated as a separate device wich uses its own driver.

The driver was tested with the following sw releases:

- **7100 (release 21.11.2023)**

Known issue: with the tested version, the readback time has been set to 4000ms due to the relatively long time it takes the device to update values internally. To change parameters via https, the satnms-service must have a valid login session. This is done automatically, however after every parameter set, the client logs itself out to keep the web interface useable for different operators at all time and not idle in a logged in state.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device

windows .

- --- Overview of the four RF SAT inputs. Lets the user enable the different inputs and set Frequency Band / Polarisation via LNB Voltage and/or 22kHz tone. View the LNA gain and LNB voltage/current.
- --- Contains Parameters for the Channels 1 to 4 and displays power, margin, BER , programs etc.
- --- Contains Parameters for the Channels 5 to 8 and displays power, margin, BER , programs etc.
- --- Contains Parameters for the Channels 9 to 12 and displays power, margin, BER , programs etc.
- --- Contains Parameters for the Channels 13 to 16 and displays power, margin, BER , programs etc.
- --- Contains Parameters for the IP TX Streams 1 to 4 and lets the user set the channel to be transmitted as well as the IP interface and port wogether with the destination address and port.
- --- Contains Parameters for the IP TX Streams 5 to 8 and lets the user set the channel to be transmitted as well as the IP interface and port wogether with the destination address and port.
- --- Contains Parameters for the IP TX Streams 9 to 12 and lets the user set the channel to be transmitted as well as the IP interface and port wogether with the destination address and port.
- --- Contains Parameters for the IP TX Streams 13 to 16 and lets the user set the channel to be transmitted as well as the IP interface and port wogether with the destination address and port.
- --- Displays the current data rate for all Ethernet interfaces including MGMT A/B and Data A/B as well as a frame counter for each Data interface.
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the unit.

- *parameter --- description*

- address --- The https address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd admin-username admin-password* of the device.

    - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
    - *admin-username* --- Username of the user with admin read/write rights on the device.

- *admin-password* --- Password of the user with admin read/write rights on the device needed for the M&C to emulate admin user inputs via https requests.

- readBackDelay --- Defines the delay the driver uses when it reads back parameters recently commanded. The delay is initialized at a proved preset value which should not be changed under normal circumstances. Per default it is set to 4000ms for this device.
- marginThreshold --- Defines the margin for each RX channel under which the device displays a warning or alarm.

9.59 Ateme-DR5000

This page describes the device driver and the device window for the Ateme DR5000 IRD, controlled via SNMP.

The Ateme IRD handles PID selection in another way than other IRDs. See paragraph "PID selection" for more information about this.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the main receiver settings and status display.
- --- Contains IP in / out parameters
- --- Contains the conditional access (BISS) parameters.
- --- Contains the parameters concerning the video decoding.
- --- Contains the parameters concerning the audio outputs and the selection of the

audio signals from the MPEG stream.

- --- Contains the parameters concerning the ASI / SDI output ports of the device
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the DR5000.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- 22kHz --- Makes the IRD apply a 22 kHz tone to the LNB power when set to ON.
- 22kHzAuto --- If set to ON, the driver switches the 22 kHz tone depending on the receive frequency. Frequencies above the 'bandEdge' value cause the 22kHz tone to be switched on, lower frequencies switch the tone off. The 22kHzAuto mode overwrites the the '22kHz' setting described above.
- lnbPower --- Selects if the IRD shall apply LNB power to the input.
- lnbVoltage --- Selects the LNB power supply voltage (13V/18V). This switches the polarization (13V=Vertical) with some LNBs.
- lnbPolSwitch --- If you set this parameter to ON, the 'lnbVoltage' parameter above becomes read-only and the LNB voltage is controlled though the 'polarization' parameter of the device driver (only makes sense with lnbPower=ON).
- loFreqHigh --- The LO frequency for the high frequency band. The software sets the appropriate LO frequency every time before it changes the receive frequency.
- loFreqLow --- The LO frequency for the low frequency band. The software sets the appropriate LO frequency every time before it changes the receive frequency.

- bandEdge --- The frequency where the software switches the LO frequencies.
- serviceHunt --- This parameter determines if the IRD will automatically choose a server / set of PIDs when tuned to a new frequency. With the Ateme IRD, this parameter also selects one of three basic operation modes for PID selection (see paragraph "PID selection" below).
- marginThreshold --- Defines the minimum s/n margin value the driver accepts as OK. s/n margin values below this threshold raise an "Margin" fault (faults.30). The margin fault detection is done by the sat-nms device driver, not by the device itself. Hence, the margin value ist stored as a saved parameter on the VLC rather than as a parameter in the IRD.
- marginOffset --- Defines an offset which will be added to the margin shown to the operator.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

PID selection

The Ateme IRD does selecting a program or a certain stream from the decoded transport stream in a different way than other IRDs do. The IRD offers three basic operation modes which do PID selection a certain manner. The configuration parameter "serviceHunt" controls this mode.

- AUTOMATIC --- In AUTOMATIC mode, the IRD automatically selects the first program in a transport stream and assigns the audio streams belonging to this program to the audio outputs one by one. The first audio stream is sent to the first embedded SDI audio and in parallel to the first AES audio output, the other audio streams are arranged accordingly. You cannot change the selected program or the audio assignments in this mode.
- AUTOSERVICE --- In AUTOSERVICE mode, the IRD tries to select the program / service which has been selected previously. No signal is output if the selected service ID is not present in the transport stream. You may select any program from the transport stream by double clicking the service name in the list on the first device window page in this mode. The audio streams for this service are selected and arranged automatically in the sam way as in AUTOMATIC mode, there is no way to change this assignment.
- PIDLOCKED --- In this mode, all decoded streams are selected manually by PID. This applies also to the video stream which only may be selected by PID in this mode, not by selecting a service. Audio streams may be selected freely by PID and arranged to the audio outputs.

9.60 Ateme-DR8400

This page describes the device driver and the device window for the Ateme DR8400 IRD, controlled via SNMP.

The Ateme IRD handles PID selection in another way than other IRDs. See paragraph "PID selection" for more information about this.

Device window pages

The following table shows which device window pages are available with this individual device

type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- Contains the main receiver settings and status display.
- --- Contains IP in / out parameters
- --- Contains the conditional access (BISS) parameters.
- --- Contains the parameters concerning the video decoding.
- --- Contains the parameters concerning the audio outputs and the selection of the audio signals from the MPEG stream.
- --- Contains the parameters concerning the ASI / SDI output ports of the device
- --- The faults page.
- --- The device info page.
- --- The maintenance page. The configuration parameters described below are set at this page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the DR8400.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- 22kHz --- Makes the IRD apply a 22 kHz tone to the LNB power when set to ON.
- 22kHzAuto --- If set to ON, the driver switches the 22 kHz tone depending on the receive frequency. Frequencies above the 'bandEdge' value cause the 22kHz tone to be switched on, lower frequencies switch the tone off. The 22kHzAuto mode overwrites the the '22kHz' setting described above.
- lnbPower --- Selects if the IRD shall apply LNB power to the input.
- lnbVoltage --- Selects the LNB power supply voltage (13V/18V). This switches the polarization (13V=Vertical) with some LNBs.

- lnbPolSwitch --- If you set this parameter to ON, the 'lnbVoltage' parameter above becomes read-only and the LNB voltage is controlled though the 'polarization' parameter of the device driver (only makes sense with lnbPower=ON).
- loFreqHigh --- The LO frequency for the high frequency band. The software sets the appropriate LO frequency every time before it changes the receive frequency.
- loFreqLow --- The LO frequency for the low frequency band. The software sets the appropriate LO frequency every time before it changes the receive frequency.
- bandEdge --- The frequency where the software switches the LO frequencies.
- marginThreshold --- Defines the minimum s/n margin value the driver accepts as OK. s/n margin values below this threshold raise an "Margin" fault (faults.30). The margin fault detection is done by the sat-nms device driver, not by the device itself. Hence, the margin value ist stored as a saved parameter on the VLC rather than as a parameter in the IRD.
- marginOffset --- Defines an offset which will be added to the margin shown to the operator.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

PID selection

The Ateme IRD does selecting a program or a certain stream from the decoded transport stream in a different way than other IRDs do. The IRD offers three basic operation modes which do PID selection a certain manner. The configuration parameter "serviceHunt" controls this mode.

- AUTOMATIC --- In AUTOMATIC mode, the IRD automatically selects the first program in a transport stream and assigns the audio streams belonging to this program to the audio outputs one by one. The first audio stream is sent to the first embedded SDI audio and in parallel to the first AES audio output, the other audio streams are arranged accordingly. You cannot change the selected program or the audio assignments in this mode.
- AUTOSERVICE --- In AUTOSERVICE mode, the IRD tries to select the program / service which has been selected previously. No signal is output if the selected service ID is not present in the transport stream. You may select any program from the transport stream by double clicking the service name in the list on the first device window page in this mode. The audio streams for this service are selected and arranged automatically in the sam way as in AUTOMATIC mode, there is no way to change this assignment.
- PIDLOCKED --- In this mode, all decoded streams are selected manually by PID. This applies also to the video stream which only may be selected by PID in this mode, not by selecting a service. Audio streams may be selected freely by PID and arranged to the audio outputs.

9.61 Ateme-Kyrion-CM5000

This page describes the device driver and the device window for the Ateme Kyrion CM5000 video encoder / modulator. The driver evaluates if a modulator module (L-Band or IF) is present at slot 6 and shows the modulator specific parameters only if a modulator module is detected.

Device window pages

The following table shows which device window pages are available with this individual device type. Tool-bar functions not mentioned here are described at the general description of device windows .

- --- RF / modulator parameters (only shown if a modulator was detected at slot 6.)
- --- MPEG output parameters
- --- C/A encryption parameters
- --- Video parameters

- --- Audio 1 parameters
- --- Audio 2 parameters
- --- Audio 3 parameters
- --- Audio 4 parameters
- --- Audio 5 parameters
- --- Audio 6 parameters
- --- Audio 7 parameters
- --- Audio 8 parameters
- --- Device fault list
- --- The faults page.
- --- The device info page.
- --- The maintenance page.

Configuration parameters

At the maintenance page of the device window there are a couple of configuration parameters which must be set to make the software talk to the encoder.

- *parameter --- description*
- address --- The SNMP address specification for the device. The full address specification consists of the following fields:*aaa.bbb.ccc.ddd:pppp read-community write-community*
  - *aaa.bbb.ccc.ddd* --- The IP address of the device in 'dotted quad' notation. This field is mandatory.
  - *pppp* --- The IP port number where the device accepts SNMP requests. The port number may be omitted, the driver uses the standard port 161 in this case.
  - *read-community* --- The SNMP read community name. This must match the read community expected by the device.
  - *write-community* --- The SNMP write community name. This must match the write community expected by the device. The write community name may be omitted, the driver uses the read community name for both, read and write in this case. If both community names are missing, the driver uses 'public' as a default for read and write community.
- loFreq --- The BUC LO frequency to be included in the displayed frequency reading. Set this to 0 if the driver shall display the transmit frequency as L-band.
- loPol --- Selects if the BUC introduces a frequency inversion. Set this to NORMAL if the LO frequency is below the transmit frequency, INVERT if the LO frequency is above.
- deviceComment --- An optional text entered here appears as an addition to the tooltip which is shown while the mouse is placed over a device icon in the GUI. The "\n" character sequence is translated into a newline character, splitting the text into multiple lines.

ristout.2.profile	CHOICE		EnumRange (MAIN SIMPLE)
ristout.2.bonding	CHOICE		EnumRange (OFF BROADCAST)
ristout.3.profile	CHOICE		EnumRange (MAIN SIMPLE)
ristout.3.bonding	CHOICE		EnumRange (OFF BROADCAST)
ristout.4.profile	CHOICE		EnumRange (MAIN SIMPLE)
ristout.4.bonding	CHOICE		EnumRange (OFF BROADCAST)
audio.1.enable	CHOICE		EnumRange (OFF ON)
audio.1.source	CHOICE		EnumRange (ANALOG SDI AES)
audio.1.inputFormat	CHOICE		EnumRange (PCM AC3 AES3 DOLBY-E)

name	*type*	*flags*	*range*
audio.1.samplingRate	CHOICE		EnumRange (48000 44100 32000)
audio.1.datarate	INTEGER		IntegerRange (32000 .. 640000)
audio.1.lang	TEXT		StringRange
audio.1.coding	CHOICE		EnumRange (MPEG LAYER2 PASS THROUGH)
audio.1.mode	CHOICE		EnumRange (STEREO MONO DUAL-MONO)
audio.1.type	CHOICE		EnumRange (DOLBY DIGITAL DOLBY DIGITAL PLUS DOLBY E AES3/SMPTE-302M)
audio.1.delay	FLOAT		DoubleRange (0 .. 0)
audio.1.gain	FLOAT		DoubleRange (0.0 .. 0.0)
audio.1.sdiMatrix	CHOICE		EnumRange (GROUP 1 - 1/2 GROUP 1 - 3/4 GROUP 2 - 1/2 GROUP 2 - 3/4 GROUP 3 - 1/2 GROUP 3 - 3/4 GROUP 4 - 1/2 GROUP 4 - 3/4)
audio.1.pid	INTEGER		IntegerRange (0 .. 8191)
audio.1.inputDetected	BOOLEAN	R/O	BooleanRange R/O (true false)
audio.1.state	CHOICE	R/O	EnumRange R/O (VALID MISSING INCOMPATIBLE INACTIVE INVALID DOLBY-E)
audio.2.enable	CHOICE		EnumRange (OFF ON)
audio.2.source	CHOICE		EnumRange (ANALOG SDI AES)
audio.2.samplingRate	CHOICE		EnumRange (48000 44100 32000)
audio.2.datarate	INTEGER		IntegerRange (32000 .. 640000)
audio.2.lang	TEXT		StringRange
audio.2.coding	CHOICE		EnumRange (MPEG LAYER2 PASS THROUGH)
